Abstract

We provide two contributions: a taxonomy of visual cluster separation factors in scatterplots, and an in-depth qualitative evaluation of two recently proposed and validated separation measures. We initially intended to use these measures to provide guidance for the use of dimension reduction (DR) techniques and visual encoding (VE) choices, but found that they failed to produce reliable results. To understand why, we conducted a systematic qualitative data study covering a broad collection of 75 real and synthetic high-dimensional datasets, four DR techniques, and three scatterplot-based visual encodings. Two authors visually inspected over 800 plots to determine whether or not the measures created plausible results. We found that they failed in over half the cases overall, and in over two-thirds of the cases involving real datasets. Using open and axial coding of failure reasons and separability characteristics, we generated a taxonomy of visual cluster separability factors. We iteratively refined its explanatory clarity and power by mapping the studied datasets and success and failure ranges of the measures onto the factor axes. Our taxonomy has four categories, ordered by their ability to influence success: Scale, Point Distance, Shape, and Position. Each category is split into Within-Cluster factors such as density, curvature, isotropy, and clumpiness, and Between-Cluster factors that arise from the variance of these properties, culminating in the overarching factor of class separation. The resulting taxonomy can be used to guide the design and the evaluation of cluster separation measures.

1. Introduction

Over a century of previous work has been devoted to creating effective and efficient algorithms for dimensionality reduction (DR), where a set of points in high-dimensional space is transformed into a more compact lower-dimensional form that preserves the important aspects of its underlying structure. These techniques include the venerable principal components analysis (PCA) [156073], the more variants of mul-

choosing DR and VE techniques [IM⁺10], but it remains an open problem to develop automatic algorithms to provide such guidance. In service of this goal, we sought to use recent measures for visual cluster separation in scatterplots [SNLH09, TAE⁺09]. These were originally developed for selecting good views within a SPLoM, but we reasoned that they should also be applicable to providing guidance for DR and VE technique choices. A previous user

Empirical Guidance on Scatterplot and Dimension Reduction Technique Choices

Michael Sedlmair, Member, IEEE, Tamara Munzner, Member, IEEE, and Melanie Tory

Abstract—To verify cluster separation in high-dimensional data, analysts often reduce the data with a dimension reduction (DR) technique, and then visualize it with 2D Scatterplots, interactive 3D Scatterplots, or Scatterplot Matrices (SPLoMs). With the goal of providing guidance between these visual encoding choices, we conducted an empirical data study in which two human coders manually inspected a broad set of 816 scatterplots derived from 75 datasets, 4 DR techniques, and the 3 previously mentioned scatterplot techniques. Each coder scored all color-coded classes in each scatterplot in terms of their separability from other classes. We analyze the resulting quantitative data with a heatmap approach, and qualitatively discuss interesting scatterplot examples. Our findings reveal that 2D scatterplots are often ‘good enough’, that is, neither SPLoM nor interactive 3D adds notably more cluster separability with the chosen DR technique. If 2D is not good enough, the most promising approach is to use an alternative DR technique in 2D. Beyond that, SPLoM occasionally adds additional value, and interactive 3D rarely helps but often hurts in terms of poorer class separation and usability. We summarize these results as a workflow model and implications for design. Our results offer guidance to analysts during the DR exploration process.

Index Terms—Dimensionality reduction, scatterplots, quantitative study

1. INTRODUCTION

High-dimensional data analysis is a common challenge amongst experts from many application domains such as science, engineering or finance. When conducting visual analysis of high-dimensional data, one typical approach is to transform the original dataset using a dimensionality reduction (DR) technique to create a lower-dimensional version that preserves as much information as possible from the original, and then visually encode only the reduced data [34]. Many DR techniques exist [45]: the most commonly used for visual data analysis include Principal Component Analysis (PCA) [22] and many variants of Multidimensional Scaling (MDS) [5, 16]. The most common visual encoding (VE) technique for showing the dimensionally reduced data is scatterplots. The three major variants are static 2D scatterplots (abbreviated here as 2D), interactive 3D scatterplots (3D for short), and static 2D scatterplot matrices (SPLoMs) showing axis-aligned views for every possible pair of reduced dimensions.

A significant amount of previous research has focused on providing broad guidance for high-dimensional data analysis [1, 36, 38, 53], and some has focused more narrowly on guidance for DR in particu-

lar: robust PCA [39], Glimmer MDS [21], and t-SNE [44]. In contrast to a typical user study collecting the judgments of a large number of people over a small number of datasets, we conducted a *data study* to collect judgments over a very broad set of data from a small number of trained coders [35]. Two coders judged the class separation of 5460 color-coded classes across 816 scatterplot visualizations.

We then engaged in generating a workflow model that can guide scatterplot choices in the DR exploration process. The workflow model reflects the main findings and implications of our study that 2D is often ‘good enough’; that is, 3D and SPLoM do not notably improve visual class separability. If 2D is not good enough, the most promising approach is to keep the same visual encoding but to try another DR technique. Switching to a SPLoM as a next step does occasionally help. Switching to 3D, however, rarely helps and often hurts; that is, it has higher time costs and often provides less class separability, even for artificial datasets specifically designed for 3D.

Abstract

We provide two contributions, a taxonomy of visual cluster separation factors in scatterplots, and an in-depth qualitative evaluation of two recently proposed and validated separation measures. We initially introduced a taxonomy of 12 factors that we hypothesized to be related to the separation of clusters in scatterplots (V2 choices), but found that they failed to produce reliable results. To understand why, we conducted a systematic qualitative data analysis concerning a broad range of 75 real and synthetic high-dimensional datasets, four synthetic datasets, and three alternative visual cluster separation measures. We found that the V2 choices did not determine whether or not the measures created plausible results. We found that they failed in over half the cases overall, and that the measures involved several different types of errors. We then proposed a new taxonomy of separation factor characteristics, with the goal of increasing the reliability of visual cluster separability factors. We iteratively refined this explanatory cluster map by mapping the studied datasets and success and failure ranges of the measures to the cluster map. We then used the cluster map to evaluate the two separation measures. We found that the Point Distance, Shape, and Position. Each category is split into Within-Cluster factors such as density, curvature, thickness, and clumpiness, and Between-Cluster factors that arise from the variance of these properties, calculated as the difference between the two clusters. The resulting taxonomy can be used to guide the design and the evaluation of cluster separation measures.

Empirical Guidance on Scatterplot and Dimension Reduction Technique Choices

Michael Sedlmair, *Member, IEEE*, Tamara Munzner, *Member, IEEE*, and Melanie Tory

Abstract—To verify cluster structure in high-dimensional data, analysts often reduce the data with a dimension reduction (DR) technique, and then visualize it with 2D Scatterplots, interactive 3D Scatterplots, or Scatterplot Matrices (SPLOMs). With the goal of providing guidance between these visual encoding choices, we conducted an empirical data study in which two human coders annotated a broad range of broad and narrow DR techniques and their associated visual encodings with a set of 100 DR-visual encodings. Each coder scored all color-coded classes in each scatterplot in terms of their separability from other classes. We analyze the resulting quantitative data with a heatmap approach, and qualitatively discuss interesting scatterplots. Our results suggest that 2D scatterplots are the best choice for visualizing DR results, but that 3D scatterplots are a good alternative if we separate with the chosen DR technique. If 2D is not good enough, the most promising approach is to use an alternative DR technique in 2D. Beyond that, SPLOM occasionally adds additional value, and interactive 3D rarely helps but often hurts in terms of performance and analysis. Our results suggest that DR visualization should be used as a workflow model and inspiration for design. Our results of course are preliminary and need to be replicated and extended as a more formal and systematic approach for design. Our results of course are preliminary and need to be replicated and extended as a more formal and systematic approach for design.

1 INTRODUCTION

High-dimensional data analysis is a common challenge amongst experts from many application domains such as science, engineering or finance. When conducting visual analysis of high-dimensional data, one of the main goals is to reduce the dimensionality of the data. Dimensionality reduction (DR) technique to create a lower-dimensional version that preserves as much information as possible from the original, and then visually encode only the reduced data [34]. Many DR techniques exist [45]; the most commonly used for visual data analysis are Principal Component Analysis (PCA) [35] and t-SNE [36]. The use of Multidimensional Scaling (MDS) [37] is also common. The use of common visual encoding (VE) technique for showing the dimensionality reduced data is scatterplots. The three major variants are static 2D scatterplots (abbreviated here as 2D), interactive 3D scatterplots (3D for short), and static 2D scatterplot matrices (SPLMs) showing axis-aligned views

A significant amount of previous research has focused on providing broad guidance for high-dimensional data analysis [1, 36, 38, 53], and some has focused more narrowly on guidance for DR in particu-

robust PCA [39], Glimmer MDS [21], and t-SNE [44]. In contrast to a typical user study collecting the judgements of a large number of people over a small number of datasets, we conducted a *data study* to collect judgements over a very broad set of data from a small number of trained coders [35]. Two coders judged the class separation of 5460 color-coded classes across 816 scatterplot visualizations.

We then engaged in generating a workflow model that can guide scatterplot choices in the DR exploration process. The workflow model reflects the main findings and implications of our study that 2D is often 'good enough'; that is, i3D and SPLM do not notably improve visual class separability. If 2D is not good enough, the most promising approach is to keep the same visual encoding but to try another DR technique. Switching to a SPLM as a next step does occasionally help. Switching to i3D, however, rarely helps and often hurts; that is, it has higher time costs and often provides less class separability, even for artificial datasets specifically designed for 3D.
