# Decision Theory: Sequential Decisions 

## CPSC 322 - Decision Theory 2

Textbook $\S 9.3$

## Lecture Overview

## (1) Recap

## (2) Sequential Decisions

## Decision Variables

- Decision variables are like random variables that an agent gets to choose the value of.
- A possible world specifies the value for each decision variable and each random variable.
- For each assignment of values to all decision variables, the measures of the worlds satisfying that assignment sum to 1 .
- The probability of a proposition is undefined unless you condition on the values of all decision variables.

## Single-Stage decisions

- Given a single decision variable, the agent can choose $D=d_{i}$ for any $d_{i} \in \operatorname{dom}(D)$.
- The expected utility of decision $D=d_{i}$ is $\mathbb{E}\left(U \mid D=d_{i}\right)$.
- An optimal single decision is the decision $D=d_{\max }$ whose expected utility is maximal:

$$
d_{\max }=\underset{d_{i} \in \operatorname{dom}(D)}{\arg \max } \mathbb{E}\left(U \mid D=d_{i}\right)
$$

## Decision Networks

- A decision network is a graphical representation of a finite sequential decision problem.
- Decision networks extend belief networks to include decision variables and utility.
- A decision network specifies what information is available when the agent has to act.
- A decision network specifies which variables the utility depends on.

## Decision Networks

- A random variable is drawn as an ellipse. Arcs into the node represent probabilistic dependence.
- A decision variable is drawn as an rectangle. Arcs into the node represent information available when the decision is made.
- A value node is drawn as a diamond. Arcs into the node represent values that the value depends on.

## Finding the optimal decision

- Suppose the random variables are $X_{1}, \ldots, X_{n}$, and utility depends on $X_{i_{1}}, \ldots, X_{i_{k}}$

$$
\begin{aligned}
\mathbb{E}(U \mid D) & =\sum_{X_{1}, \ldots, X_{n}} P\left(X_{1}, \ldots, X_{n} \mid D\right) U\left(X_{i_{1}}, \ldots, X_{i_{k}}\right) \\
& =\sum_{X_{1}, \ldots, X_{n}} \prod_{i=1}^{n} P\left(X_{i} \mid p X_{i}, D\right) U\left(X_{i_{1}}, \ldots, X_{i_{k}}\right)
\end{aligned}
$$

To find the optimal decision:

- Create a factor for each conditional probability and for the utility
- Sum out all of the random variables
- This creates a factor on $D$ that gives the expected utility for each $D$
- Choose the $D$ with the maximum value in the factor.

## Example Initial Factors

| Which Way | Accident | Probability |
| :--- | :--- | :--- |
| long | true | 0.01 |
| long | false | 0.99 |
| short | true | 0.2 |
| short | false | 0.8 |

| Which Way | Accident | Wear Pads | Utility |
| :--- | :--- | :--- | :--- |
| long | true | true | 30 |
| long | true | false | 0 |
| long | false | true | 75 |
| long | false | false | 80 |
| short | true | true | 35 |
| short | true | false | 3 |
| short | false | true | 95 |
| short | false | false | 100 |

## Example Initial Factors

| Which Way | Accident | Probability |
| :--- | :--- | :--- |
| long | true | 0.01 |
| long | false | 0.99 |
| short | true | 0.2 |
| short | false | 0.8 |

| Which Way | Accident | Wear Pads | Utility |
| :--- | :--- | :--- | :--- |
| long | true | true | 30 |
| long | true | false | 0 |
| long | false | true | 75 |
| long | false | false | 80 |
| short | true | true | 35 |
| short | true | false | 3 |
| short | false | true | 95 |
| short | false | false | 100 |

Sum out Accident:

| Which Way | Wear pads | Value |
| :--- | :--- | :--- |
| long | true | $0.01^{*} 30+0.99^{*} 75=74.55$ |
| long | false | $0.01^{*} 0+0.99^{*} 80=79.2$ |
| short | true | $0.2^{*} 35+0.8 * 95=83$ |
| short | false | $0.2^{*} 3+0.8^{*} 100=80.6$ |

## Example Initial Factors

| Which Way | Accident | Probability |
| :--- | :--- | :--- |
| long | true | 0.01 |
| long | false | 0.99 |
| short | true | 0.2 |
| short | false | 0.8 |

| Which Way | Accident | Wear Pads | Utility |
| :--- | :--- | :--- | :--- |
| long | true | true | 30 |
| long | true | false | 0 |
| long | false | true | 75 |
| long | false | false | 80 |
| short | true | true | 35 |
| short | true | false | 3 |
| short | false | true | 95 |
| short | false | false | 100 |

Sum out Accident:

| Which Way | Wear pads | Value |
| :--- | :--- | :--- |
| long | true | $0.01^{*} 30+0.99^{*} 75=74.55$ |
| long | false | $0.01^{*} 0+0.99 * 80=79.2$ |
| short | true | $0.2^{*} 35+0.8 * 95=83$ |
| short | false | $0.2^{*} 3+0.8 * 100=80.6$ |

## Example Initial Factors

| Which Way | Accident | Probability |
| :--- | :--- | :--- |
| long | true | 0.01 |
| long | false | 0.99 |
| short | true | 0.2 |
| short | false | 0.8 |

| Which Way | Accident | Wear Pads | Utility |
| :--- | :--- | :--- | :--- |
| long | true | true | 30 |
| long | true | false | 0 |
| long | false | true | 75 |
| long | false | false | 80 |
| short | true | true | 35 |
| short | true | false | 3 |
| short | false | true | 95 |
| short | false | false | 100 |

Sum out Accident:

| Which Way | Wear pads | Value |
| :--- | :--- | :--- |
| long | true | $0.01^{*} 30+0.99^{*} 75=74.55$ |
| long | false | $0.01^{*} 0+0.99 * 80=79.2$ |
| short | true | $0.2^{*} 35+0.8^{*} 95=83$ |
| short | false | $0.2^{*} 3+0.8^{*} 100=80.6$ |

Thus the optimal policy is to take the short way and wear pads, with an expected utility of 83 .

## Lecture Overview

## (1) Recap

(2) Sequential Decisions

## Sequential Decisions

- An intelligent agent doesn't make a multi-step decision and carry it out without considering revising it based on future information.
- A more typical scenario is where the agent: observes, acts, observes, acts, ...
- just like your final homework!
- Subsequent actions can depend on what is observed.
- What is observed depends on previous actions.
- Often the sole reason for carrying out an action is to provide information for future actions.
- For example: diagnostic tests, spying.

## Sequential decision problems

- A sequential decision problem consists of a sequence of decision variables $D_{1}, \ldots, D_{n}$.
- Each $D_{i}$ has an information set of variables $p D_{i}$, whose value will be known at the time decision $D_{i}$ is made.
- What should an agent do?
- What an agent should do at any time depends on what it will do in the future.
- What an agent does in the future depends on what it did before.

## Policies

- A policy specifies what an agent should do under each circumstance.
- A policy is a sequence $\delta_{1}, \ldots, \delta_{n}$ of decision functions

$$
\delta_{i}: \operatorname{dom}\left(p D_{i}\right) \rightarrow \operatorname{dom}\left(D_{i}\right) .
$$

This policy means that when the agent has observed $O \in \operatorname{dom}\left(p D_{i}\right)$, it will do $\delta_{i}(O)$.

## Expected Value of a Policy

- Possible world $\omega$ satisfies policy $\delta$, written $\omega \models \delta$, if the world assigns the value to each decision node that the policy specifies.
- The expected utility of policy $\delta$ is

$$
\mathbb{E}(U \mid \delta)=\sum_{\omega \models \delta} P(\omega) U(\omega)
$$

- An optimal policy is one with the highest expected utility:

$$
\delta^{*} \in \underset{\delta}{\arg \max } \mathbb{E}(U \mid \delta) .
$$
