 Bayesian Game Setting

- Extend the social choice setting to a new setting where agents can't be relied upon to disclose their preferences honestly.
- Start with a set of agents in a Bayesian game setting (but no actions).

Definition (Bayesian game setting)

A Bayesian game setting is a tuple (N, O, Θ, p, u) , where

- N is a finite set of n agents;
- O is a set of outcomes;
- $\Theta = \Theta_1 \times \cdots \times \Theta_n$ is a set of possible joint type vectors;
- p is a (common prior) probability distribution on Θ ; and
- $u = (u_1, \ldots, u_n)$, where $u_i : O \times \Theta \mapsto \mathbb{R}$ is the utility function for each player *i*.

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
Mechan	ism Design			

Definition (Mechanism)

A mechanism (for a Bayesian game setting $(N,O,\Theta,p,u))$ is a pair (A,M), where

- $A = A_1 \times \cdots \times A_n$, where A_i is the set of actions available to agent $i \in N$; and
- $M: A \mapsto \Pi(O)$ maps each action profile to a distribution over outcomes.

Thus, the designer gets to specify

- the action sets for the agents (though they may be constrained by the environment)
- the mapping to outcomes, over which agents have utility
- can't change outcomes; agents' preferences or type spaces

Implementation in Dominant Strategies

Definition (Implementation in dominant strategies)

Given a Bayesian game setting (N, O, Θ, p, u) , a mechanism (A, M) is an implementation in dominant strategies of a social choice function C (over N and O) if for any vector of utility functions u, the game has an equilibrium in dominant strategies, and in any such equilibrium a^* we have $M(a^*) = C(u)$.

Implementation in Bayes-Nash equilibrium

Definition (Bayes–Nash implementation)

Given a Bayesian game setting (N, O, Θ, p, u) , a mechanism (A, M) is an implementation in Bayes–Nash equilibrium of a social choice function C (over N and O) if there exists a Bayes–Nash equilibrium of the game of incomplete information (N, A, Θ, p, u) such that for every $\theta \in \Theta$ and every action profile $a \in A$ that can arise given type profile θ in this equilibrium, we have that $M(a) = C(u(\cdot, \theta))$.

Properti	es			

Forms of implementation

- Direct Implementation: agents each simultaneously send a single message to the center
- Indirect Implementation: agents may send a sequence of messages; in between, information may be (partially) revealed about the messages that were sent previously like extensive form

We can also insist that our mechanism satisfy properties like the following:

- individual rationality: agents are better off playing than not playing
- budget balance: the mechanism gives away and collects the same amounts of money
- truthfulness: agents honestly report their types

5 Risk Attitudes

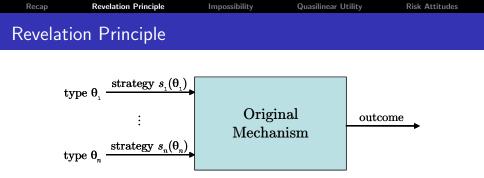

< 注→ < 注

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
Revelat	ion Principle			

- It turns out that any social choice function that can be implemented by any mechanism can be implemented by a truthful, direct mechanism!
- Consider an arbitrary, non-truthful mechanism (e.g., may be indirect)

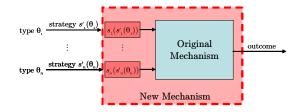

- It turns out that any social choice function that can be implemented by any mechanism can be implemented by a truthful, direct mechanism!
- Consider an arbitrary, non-truthful mechanism (e.g., may be indirect)

- It turns out that any social choice function that can be implemented by any mechanism can be implemented by a truthful, direct mechanism!
- Consider an arbitrary, non-truthful mechanism (e.g., may be indirect)
- Recall that a mechanism defines a game, and consider an equilibrium $s=(s_1,\ldots,s_n)$

イロン イヨン イヨン イヨン

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
Revelat	ion Principle			

- We can construct a new direct mechanism, as shown above
- This mechanism is truthful by exactly the same argument that s was an equilibrium in the original mechanism
- "The agents don't have to lie, because the mechanism already lies for them."

Computational Criticism of the Revelation Principle

• computation is pushed onto the center

- often, agents' strategies will be computationally expensive
 - e.g., in the shortest path problem, agents may need to compute shortest paths, cutsets in the graph, etc.
- since the center plays equilibrium strategies for the agents, the center now incurs this cost
- if computation is intractable, so that it cannot be performed by agents, then in a sense the revelation principle doesn't hold
 - agents can't play the equilibrium strategy in the original mechanism
 - however, in this case it's unclear what the agents will do

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
Discussi	on of the Reve	lation Princ	ciple	

- The set of equilibria is not always the same in the original mechanism and revelation mechanism
 - of course, we've shown that the revelation mechanism does have the original equilibrium of interest
 - however, in the case of indirect mechanisms, even if the indirect mechanism had a unique equilibrium, the revelation mechanism can also have new, bad equilibria
- So what is the revelation principle good for?
 - recognition that truthfulness is not a restrictive assumption
 - for analysis purposes, we can consider only truthful mechanisms, and be assured that such a mechanism exists
 - recognition that indirect mechanisms can't do (inherently) better than direct mechanisms

Impossibility Result

Theorem (Gibbard-Satterthwaite)

Consider any social choice function C of N and O. If:

- 0 |O| > 3 (there are at least three outcomes);
- 2 C is onto; that is, for every $o \in O$ there is a preference profile $[\succ]$ such that $C([\succ]) = o$ (this property is sometimes also called citizen sovereignty); and
- 3 C is dominant-strategy truthful,

then C is dictatorial.

• E • • E • •

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
What d	oes this mean?			

- We should be discouraged about the possibility of implementing arbitrary social-choice functions in mechanisms.
- However, in practice we can circumvent the Gibbard-Satterthwaite theorem in two ways:
 - use a weaker form of implementation
 - note: the result only holds for dominant strategy implementation, not e.g., Bayes-Nash implementation
 - relax the onto condition and the (implicit) assumption that agents are allowed to hold arbitrary preferences

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
Quasilin	ear Utility			

Definition (Quasilinear preferences)

Agents have quasilinear preferences in an n-player Bayesian game when the set of outcomes is

$$O = X \times \mathbb{R}^n$$

for a finite set X, and the utility of an agent i given joint type θ is given by

$$u_i(o,\theta) = u_i(x,\theta) - f_i(p_i),$$

where o = (x, p) is an element of O, $u_i : X \times \Theta \mapsto \mathbb{R}$ is an arbitrary function and $f_i : \mathbb{R} \mapsto \mathbb{R}$ is a strictly monotonically increasing function.

Recap	Revelation Principle	Impossibility	Quasilinear Utility	Risk Attitudes
Quasilin	lear utility			

•
$$u_i(o,\theta) = u_i(x,\theta) - f_i(p_i)$$

• We split the mechanism into a choice rule and a payment rule:

- $x \in X$ is a discrete, non-monetary outcome
- $p_i \in \mathbb{R}$ is a monetary payment (possibly negative) that agent i must make to the mechanism
- Implications:

Quasilin	lear utility			

•
$$u_i(o,\theta) = u_i(x,\theta) - f_i(p_i)$$

• We split the mechanism into a choice rule and a payment rule:

- $x \in X$ is a discrete, non-monetary outcome
- $p_i \in \mathbb{R}$ is a monetary payment (possibly negative) that agent i must make to the mechanism
- Implications:
 - $u_i(x, \theta)$ is not influenced by the amount of money an agent has
 - agents don't care how much others are made to pay (though they *can* care about how the choice affects others.)

Fun gan	ne			

- Look at your piece of paper: it contains an integer \boldsymbol{x}
- Go around the room offering everyone the following gamble:
 - ${\scriptstyle \bullet} \,$ they pay you x
 - you flip a coin:
 - $\bullet\,$ heads: they win and get paid 2x
 - tails: they lose and get nothing.
 - Players can accept the gamble or decline.
 - Answer honestly (imagining the amounts of money are real)
 - play the gamble to see what would have happened.
 - Keep track of:
 - Your own "bank balance" from others' gambles you accepted.
 - The number of people who accepted your offer.

- How much is \$1 worth?
 - What are the units in which this question should be answered?
