**The public microarray data increases by 3 folds per year**

# Graph-based Approach for the Integrative Microarray Analysis

# Frequent Subgraph Mining Problem is hard!

**Problem formulation:** Given  $n$  graphs, identify subgraphs which occur in at least  $m$  graphs ( $m \leq n$ )

**Our graphs are massive!**

The traditional pattern growth approach (expand frequent subgraph of  $k$  edges to  $k+1$  edges) would not work, since the time and memory requirements increase exponentially with increasing size of patterns and increasing number of networks.

# Novel Algorithms to identify diverse frequent network patterns

# The common pattern growth approach

Find a frequent subgraph of  $k$  edges, and expand it to  $k+1$  edge to check occurrence frequency

- Koyuturk M., Grama A. & Szpankowski W. *An efficient algorithm for detecting frequent subgraphs in biological networks*. ISMB 2004
- Yan, Zhou, and Han. *Mining Closed Relational Graphs with Connectivity Constraints*. ICDE 2005

## **Problem of the Pattern-growth approach**

The time and memory requirements increase exponentially with increasing size of patterns and increasing number of networks. The number of frequent dense subgraphs is explosive when there are very large frequent dense subgraphs, e.g., subgraphs with hundreds of edges.

# Problem of the Pattern-growth approach

## Pattern Expansion

$k \rightarrow k+1$

# Our solution

We develop a novel algorithm, called *CODENSE*, to mine frequent *coherent dense* subgraphs. The target subgraphs have three characteristics:

- (1) All edges occur in  $\geq k$  graphs (*frequency*)
- (2) All edges should exhibit correlated occurrences in the given graph set. (*coherency*)
- (3) The subgraph is dense, where density  $d$  is higher than a threshold  $\gamma$  and  $d = 2m / (n(n-1))$  (*density*)  
*m*: #edges, *n*: #nodes

# CODENSE: Mine coherent dense subgraph

(1) Builds a summary graph by eliminating infrequent edges

# CODENSE: Mine coherent dense subgraph

## (2) Identify dense subgraphs of the summary graph

**Observation:** If a frequent subgraph is dense, it must be a dense subgraph in the summary graph. However, the reverse conclusion is not true.

# CODENSE: Mine coherent dense subgraph

(3) Construct the edge occurrence profiles for each dense summary subgraph

Step 3

E	G1	G2	G3	G4	G5	G6
c-e	0	0	1	1	0	1
c-f	0	1	0	1	1	1
c-h	0	0	0	1	1	1
c-i	0	0	1	1	1	0
e-f	0	0	0	1	1	1
...	...	...	...	...	...	...

edge occurrence profiles

# CODENSE: Mine coherent dense subgraph

(4) builds a second-order graph for each dense summary subgraph

E	G1	G2	G3	G4	G5	G6
c-e	0	0	1	1	1	1
c-f	0	1	0	1	1	1
c-h	0	0	0	1	1	1
c-i	0	0	1	1	1	0
e-f	0	0	0	1	1	1
...	...	...	...	...	...	...

edge occurrence profiles

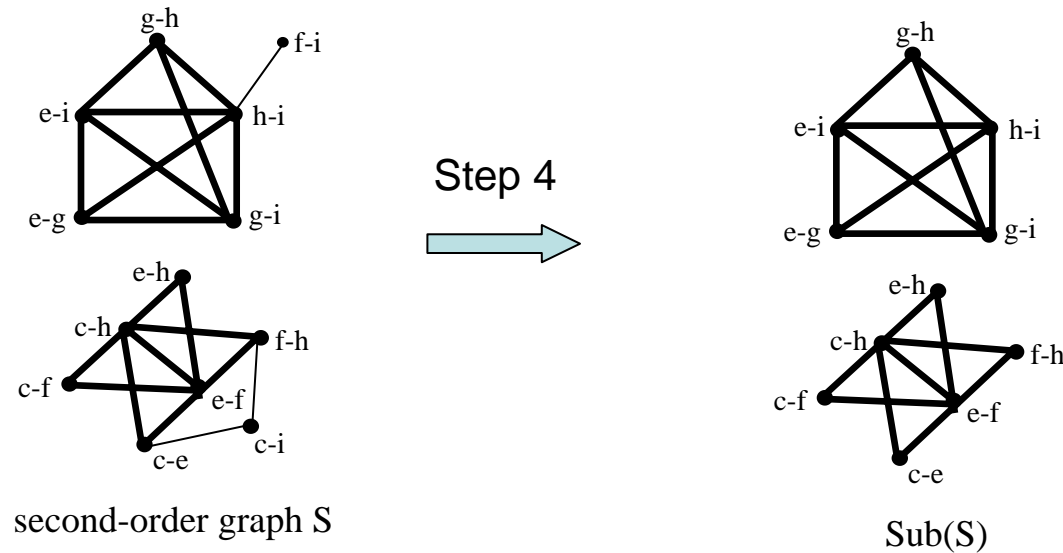

Step 4

second-order graph S

# CODENSE: Mine coherent dense subgraph

(5) Identify dense subgraphs of the second-order graph

**Observation:** if a subgraph is coherent (its edges show high correlation in their occurrences across a graph set), then its 2nd-order graph must be dense.

# CODENSE: Mine coherent dense subgraph

## (6) Identify the coherent dense subgraphs

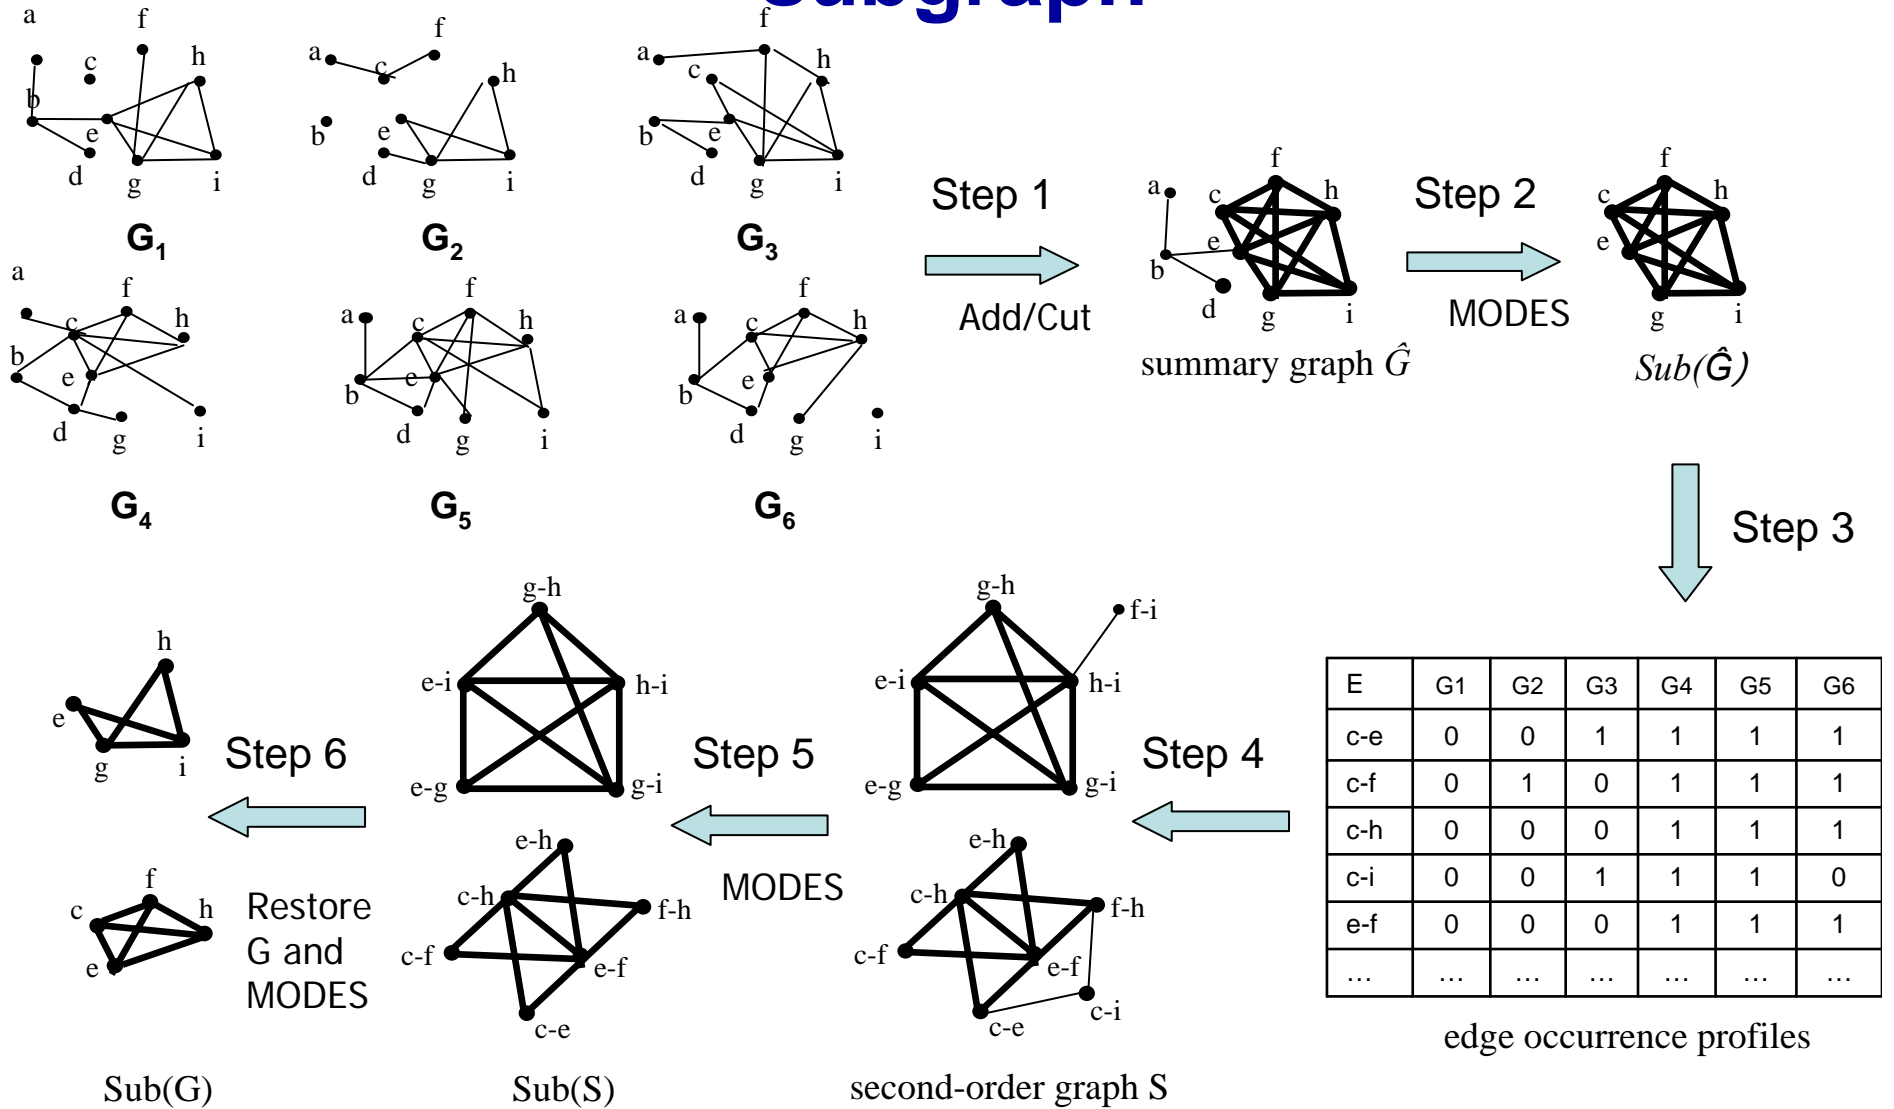

# Our solution

The identified subgraphs by definition satisfy the three criteria:

- (1) All edges occur in  $\geq k$  graphs **(frequency)**
- (2) All edges should exhibit correlated occurrences in the given graph set. **(coherency)**
- (3) The subgraph is dense, where density  $d$  is higher than a threshold  $\gamma$  and  $d=2m/(n(n-1))$  **(density)**  
 *$m$ : #edges,  $n$ : #nodes*

# CODENSE: Mine coherent dense subgraph

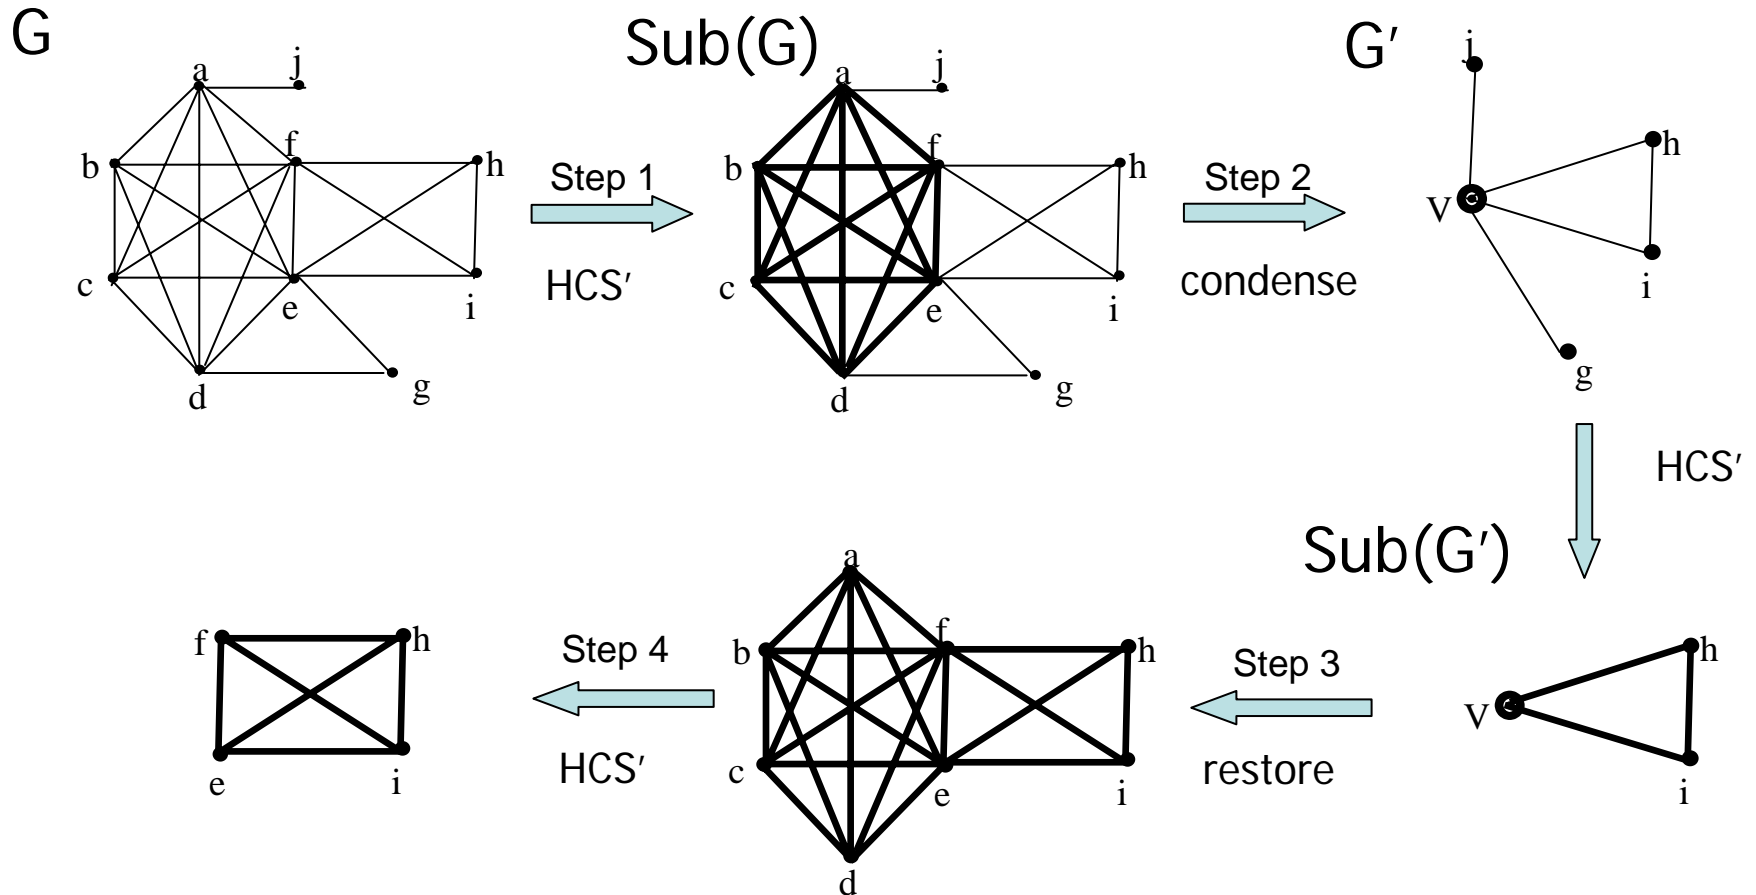

# CODENSE

The design of CODENSE can solve the **scalability** issue. Instead of mining each biological network individually, CODENSE compresses the networks into two meta-graphs and performs clustering in these two graphs only. Thus, **CODENSE can handle any large number of networks.**

# MODES: Mine overlapped dense subgraph

# Applying CoDense to 39 yeast microarray data sets

	$c_1$	$c_2$	...	$c_m$
$g_1$	.1	.2	...	.2

# Functional annotation

## Functional Annotation (Validation)

**Method:** leave-one-out approach - masking a known gene to be unknown, and assign its function based on the other genes in the subgraph pattern.

**Functional categories:** 166 functional categories at GO level at least 6

**Results:** 448 predictions with accuracy of 50%

## Functional Annotation (Prediction)

We made functional predictions for 169 genes, covering a wide range of functional categories, e.g. amino acid biosynthesis, ATP biosynthesis, ribosome biogenesis, vitamin biosynthesis, etc. A significant number of our predictions can be supported by literature.

# However...

- How about frequent non-dense graphs?
  - Many biological modules may form paths
- How about subgraphs which are coherent across only a subset of the graphs?
  - Not all modules are activated across all conditions, and genes may form modules with diff. other genes under diff. conditions

**Network Biclustering:**  
Identify frequent subgraphs across  
massive graphs

*Huang et al, ISMB 2007*

## Using 65 human co-expression network as an illustration example

- 65 co-expression networks generated from 65 microarray data sets
- each graph contains 8297 genes, and 1%-10% edges of a complete graph

# Basically, it is a biclustering problem

# Network Biclustering

- Objective function

$$f = \frac{c'}{mn + \lambda c}$$

$c'$ : number of 1 in the bicluster

$c$ : number of 1 in the whole matrix

$mn$ : size of the bicluster

$\lambda$ : regularization factor

However, the matrix is very large with millions of edges ...

We will first identify robust seed to narrow down the search space

# Identify Biclusters seed

The property of relation graphs: edge labels are unique.

Hence, each graph can be treated as a collection of items

Thus, Frequent subgraph Mining can be modeled as frequent item set mining

Problem: current frequent item set mining algorithms can only efficiently mine across many small item sets

In our problem, we have 65 very large item sets...

We use a trick....

# Identify Bicluster seed

Edge occurrence profiles:

#### Summary

Spontaneous basal-like human breast cancer is associated with a high frequency of X-chromosomal abnormalities, including deletions of the X-chromosomal gene *BRCA1*. Here, we report that, in addition to these mixed agonist/antagonist actions of tamoxifen, it also has some deleterious side effects, such as an increased risk of endometrial cancer and thromboembolic events (4). One of the primary functions of the ERs (ERα and ERβ) is their ability to regulate gene transcription in a tissue-specific manner.

#### Abstract

The beneficial effect of the selective estrogen receptor (ER) modulator tamoxifen in the treatment and prevention of breast cancer is assumed to be through its ability to antagonize the stimulatory actions of estrogen, although tamoxifen can also have some estrogen-like agonist effects. Here, we report that, in addition to these mixed agonist/antagonist actions of tamoxifen, it also has some deleterious side effects, such as an increased risk of endometrial cancer and thromboembolic events (4). One of the primary functions of the ERs (ERα and ERβ) is their ability to regulate gene transcription in a tissue-specific manner.

# Three types of transcription cascades

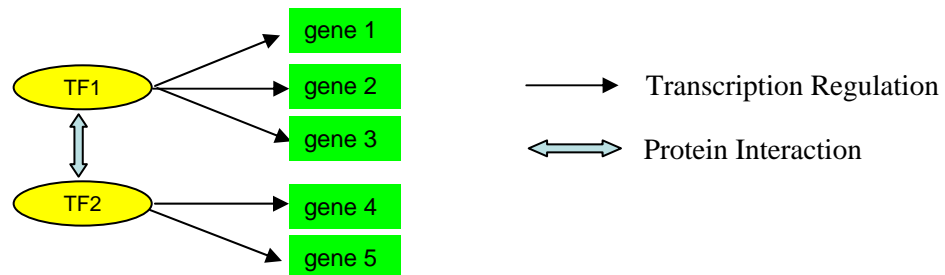

Type I

Type II

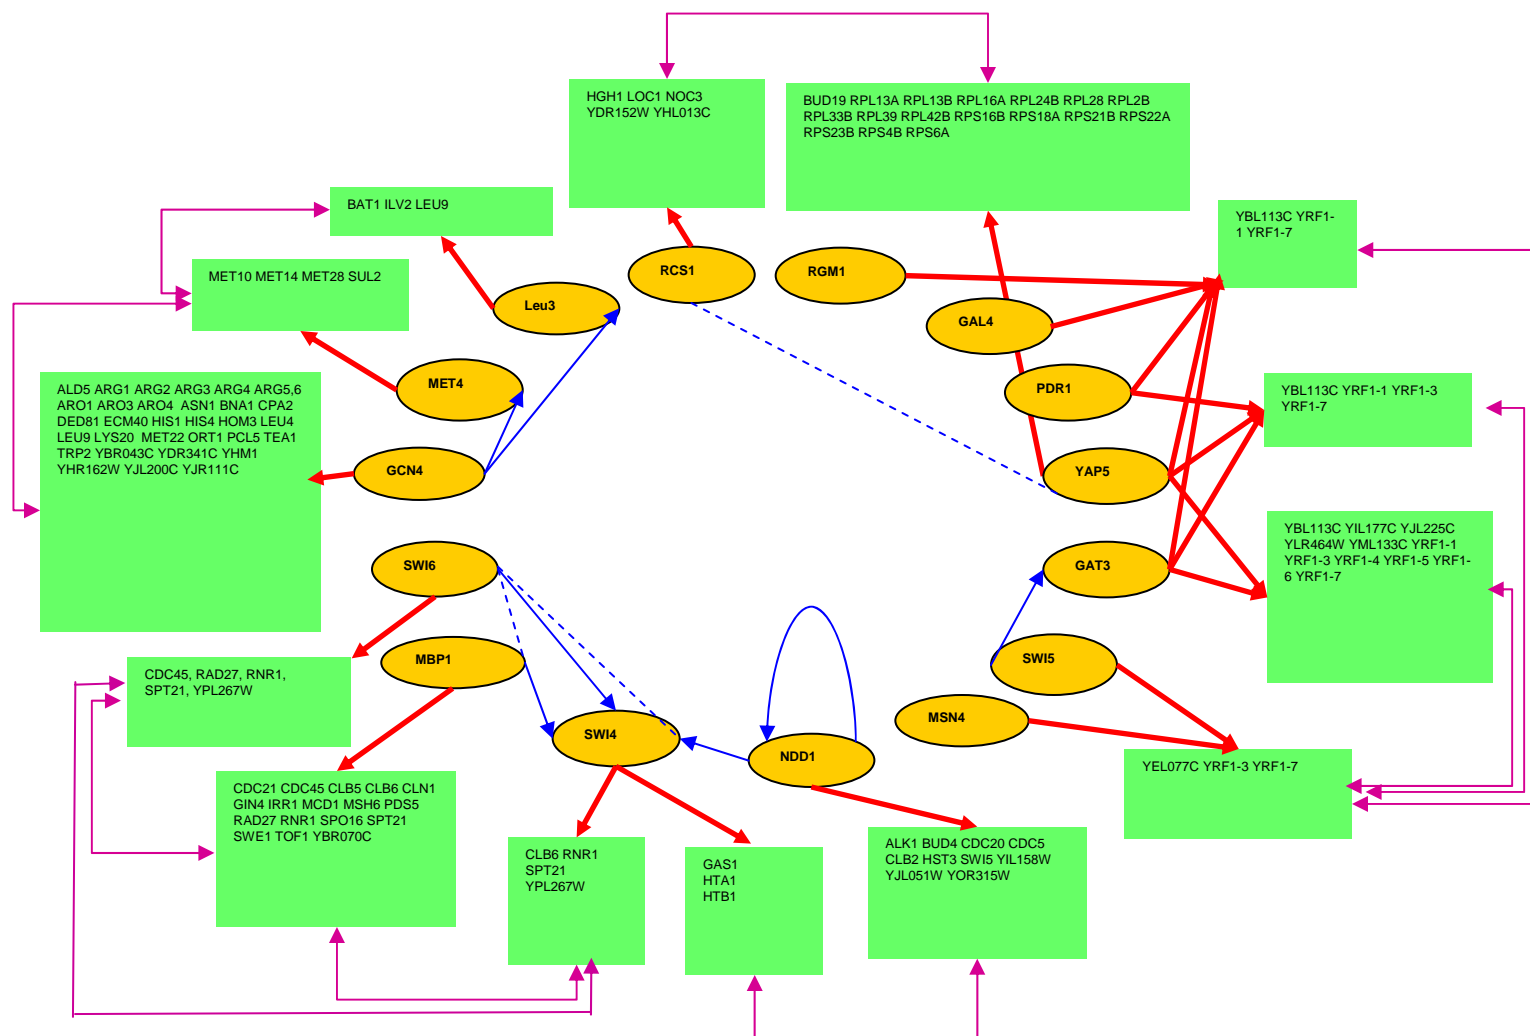

Type III

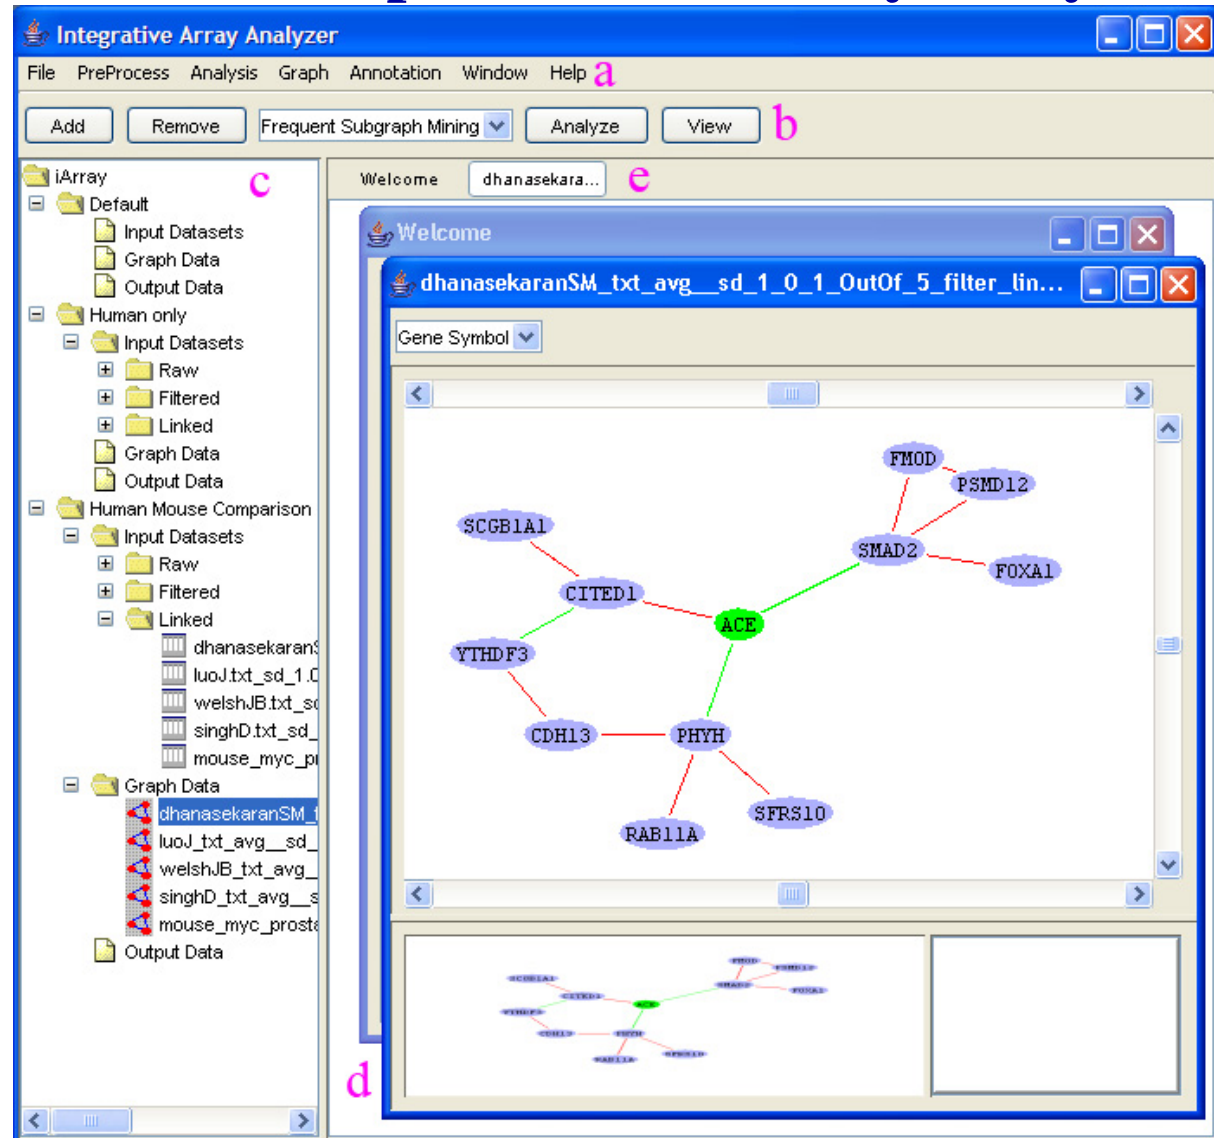

## Applying to 39 yeast microarray data sets

- We identified 60 transcription modules. Among them, we found 34 pairs that showed high 2nd-order correlation. A significant portion (29%,  $p$ -value  $< 10^{-5}$  by Monte Carlo simulation ) of those modules pairs are participants in transcription cascades: 2 pairs in Type I, 8 pairs in Type II, and 3 pairs in type III cascades. In fact, these transcription cascades inter-connect into a partial cellular regulatory network.
