CPSC 340: Machine Learning and Data Mining

K-Means Clustering Fall 2016

Admin

- Assignment 1 is due now!
 - 1 late day to hand it in before Monday's class.
 - 2 late days to hand it in before Wednesday's class.
 - 3 late days to hand it in before Friday of next week's class.
 - 0 after that.
- Assignment 2 coming next week.

Random Forests

- Random forests are one of the best 'out of the box' classifiers.
- Fit deep decision trees to random bootstrap samples of data, base splits on random subsets of the features, and classify using mode.

Random Forests

- Random forests are one of the best 'out of the box' classifiers.
- Fit deep decision trees to random bootstrap samples of data, base splits on random subsets of the features, and classify using mode.

End of Part 1: Key Concepts

- Fundamental ideas:
 - Training vs. test error.
 - Golden rule of ML.
 - Fundamental trade-off.
 - Validation sets and cross-validation.
 - Parametric vs. non-parametric.
 - No free lunch theorem.
 - Ensemble methods.
- Methods that we focused on:
 - Decision trees (greedy recursive splitting using decision stumps).
 - Naïve Bayes (generative classifier based on conditional independence).
 - K-nearest neighbours (non-parametric classifier with universal consistency).
 - Random forests (averaging plus randomization to reduce overfitting).

Application: Classifying Cancer Types

• "I collected gene expression data for 1000 different types of cancer cells, can you tell me the different classes of cancer?"

- We are not given the class labels y, but want meaningful labels.
- An example of unsupervised learning.

Unsupervised Learning

- Supervised learning:
 - We have features x_i and class labels y_i .
 - Write a program that produces y_i from x_i .
- Unsupervised learning:
 - We only have x_i values, but no explicit target labels.
 - You want to do 'something' with them.
- Some unsupervised learning tasks:
 - Outlier detection: Is this a 'normal' x_i ?
 - Data visualization: What does the high-dimensional X look like?
 - Association rules: Which x_{ii} occur together?
 - Latent-factors: What 'parts' are the x_i made from?
 - Ranking: Which are the most important x_i?
 - Clustering: What types of x_i are there?

Clustering

- Clustering:
 - Input: set of objects described by features x_i .
 - Output: an assignment of objects to 'groups'.
- Unlike classification, we are not given the 'groups'.
 - Algorithm must discover groups.
- Example of groups we might discover in e-mail spam:
 - 'Lucky winner' group.
 - 'Weight loss' group.
 - 'Nigerian prince' group.

Clustering Example

Clustering Example

Data Clustering

- General goal of clustering algorithms:
 - Objects in the same group should be 'similar'.
 - Objects in different groups should be 'different'.
- But the 'best' clustering is hard to define:
 - We don't have a test error.
 - Generally, there is no 'best' method in unsupervised learning.
 - Means there are lots of methods: we'll focus on important/representative ones.
- Why cluster?
 - You could want to know what the groups are.
 - You could want a 'prototype' example for each group.
 - You could want to find the group for a new example x.
 - You could want to find objects related to a new example x.

Clustering of Epstein-Barr Virus

http://jvi.asm.org/content/86/20/11096.abstract

Other Clustering Applications

- NASA: what types of stars are there?
- Biology: are there sub-species?
- Documents: what kinds of documents are on my HD?
- Commercial: what kinds of customers do I have?

http://www.eecs.wsu.edu/~cook/dm/lectures/l9/index.html http://www.biology-online.org/articles/canine_genomics_genetics_running/figures.htm

K-Means

- Most popular clustering method is k-means.
- Input:
 - The number of clusters 'k'.
 - Initial guesses of the center ("mean") of each cluster.
- Algorithm:
 - Assign each x_i to its closest mean.
 - Update the means based on the assignment.
 - Repeat until convergence.

K-Means Issues

- Guaranteed to converge when using Euclidean distance.
- New object are assigned to nearest mean to cluster them.
- Assumes you know number of clusters 'k'.
 - Lots of heuristics to pick 'k', none satisfying:
 - https://en.wikipedia.org/wiki/Determining_the_number_of_clusters_in_a_data_set
- Each object is assigned to one (and only one) cluster:
 - No possibility for overlapping clusters or leaving objects unassigned.
- It may converge to sub-optimal solution...

K-Means Clustering with Different Initialization

- Classic approach to dealing with sensitivity to initialization:
 Try several different random starting points, choose the 'best'.
- We'll see a more clever approach next time...

Cost of K-means

• Bottleneck is calculating distance from each x_i to each mean w_c:

$$D(x_i, w_c) = \sqrt{\frac{d}{2}(x_{ij} - w_{cj})^2} \quad Vector ocentric of the scentric of the state of$$

Cost of K-means

Bottleneck is calculating distance from each x_i to each mean w_c:

$$D(x_i, w_c) = \sqrt{\sum_{j=1}^d (x_{ij} - w_{cj})^2}$$

- Each time we do this costs O(d) to go through all features.
- For each of the 'n' objects, we compute the distance to 'k' clusters.
- Total cost of assigning objects to clusters is O(ndk).
 - Fast if k is not too large.
- Updating means is cheaper: O(nd). - For each cluster 'c', compute $w_c = \frac{1}{n_c} \sum_{i \in C} X_i$, Loop over objects in cluster. - Number of objects in cluster 'c'

Vector Quantization

- K-means originally comes from signal processing.
- Designed for vector quantization:
 - Replace 'vectors' (objects) with a set of 'prototypes' (means).
- Example:
 - Facebook places.
 - What sizes of clothing should I make?

http://wannabite.com/wp-content/uploads/2014/10/ragu-pasta-sauce-printable-coupon.jp

- Usual RGB representation of a pixel's color: three 8-bit numbers.
 - For example, [241 13 50] = .
 - Can apply k-means to find set of prototype colours.

- Usual RGB representation of a pixel's color: three 8-bit numbers.
 - − For example, [241 13 50] = .
 - Can apply k-means to find set of prototype colours.

- Usual RGB representation of a pixel's color: three 8-bit numbers.
 - − For example, [241 13 50] = .
 - Can apply k-means to find set of prototype colours.

- Usual RGB representation of a pixel's color: three 8-bit numbers.
 - For example, [241 13 50] = .
 - Can apply k-means to find set of prototype colours.

What is K-Means Doing?

OCluster of example "

- We can interpret K-Means as trying to minimize an objective:
 - Total sum of squared distances from object x_i to their centers $w_{c(i)}$:

$$f(w_{i}, w_{2}, \dots, w_{k}, c(1), c(2), \dots, c(n)) = \sum_{j=1}^{n} \sum_{j=1}^{d} (x_{ij} - w_{ij})^{2}$$

- The k-means steps:
 - Optimally update cluster assignments c(i).
 - Optimally update means w_c.
- Convergence follows because:
 - Each step does not increase the objective.
 - There are a finite number of assignments to k clusters.

K-Medians Clustering

- With other distances, k-means may not converge.
- However, changing objective function gives convergent algorithms.
- E.g., we can use the L1-norm:

$$\sum_{i=1}^{n} \sum_{j=1}^{d} |x_{ij} - w_{c(i)j}|$$

لرز،

- A 'k-medians' algorithm based on the L1-norm:
 - Cluster assignment based on the L1-norm (nearest median).
 - Update 'medians' as median value (dimension-wise) of each cluster.
- This approach is more robust to outliers.

Summary

- Unsupervised learning: fitting data without explicit labels.
- Clustering: finding 'groups' of related objects.
- K-means: simple iterative clustering strategy.
- Vector quantization: replacing measurements with 'prototypes'.
- K-medians: generalization to other distance functions.

- Next time:
 - Non-parametric clustering.
