Reading

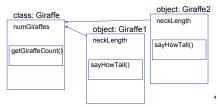

- This week reading: 2.11-2.12, 9.5-9.8,10.9-10.10
  - 5.1-5.2, 11.5, 12.2-12.3 (2nd edition)
  - we will not get through all this material in lecture
  - minimal/no coverage on final

  - weekly reading question still due last class Wed 4/14

# Recap: Static Fields/Methods

- Static fields belong to whole class
  - nonstatic fields belong to instantiated object
  - Static methods can only use static fields
  - nonstatic methods can use either nonstatic or static fields

Subclasses inherits but cannot directly access

Protected variables can be directly accessed

from declaring class and any classes derived

private fields or variables of superclass

## Recap: Variable Types and Scope

- Static variables
- declared within class
- associated with class, not instance
- Instance variables
- declared within class
- associated with instance
- accessible throughout object, lifetime of object
- declared within method
- accessible throughout method, lifetime of method
- Parameters
  - declared in parameter list of method
- accessible throughout method, lifetime of method

## **Recap: Inheritance**

- Inheritance: process by which new class is derived from existing one
  - fundamental principle of object-oriented programming
- Create new child class (subclass) that extends existing parent one (superclass)
  - inherits all methods and variables
  - except constructor
  - can just add new variables and methods

**Recap: Inheritance and Constructors** 

public CokeMachine2000(int n) { public void loadCoke(int n) numberOfCans = numberOfCans + n;
System.out.println("Adding " + n + " cans to this machine");

- Subclass (child class) inherits all methods except constructor methods from superclass (parent class)
- Using reserved word super in subclass constructor tells Java to call appropriate constructor method of superclass

**Recap: Inheritance and Scope** 

**Some Coke Machine History** 

early Coke Machine

- mechanical
- · sealed unit, must be reloaded at factory
- no protection against vandalism

**Some Coke Machine History** 

Coke Machine 2000

- electro-mechanical
- · can be reloaded on site
- · little protection against vandalism

# Some Coke Machine History

Coke Machine UA\*

- · prototype cyberhuman intelligent mobile autonomous vending machine can reload itself in transit
- · vandalism? bring it on
- \* Urban Assault

# Some Coke Machine History Coke Machine UA

from it

Assuming that previous generation CokeMachine simulations have wimpy vandalize() methods built-in to model their gutless behavior when faced with a crowbar-wielding human, how do we create the UA class with true vandal deterrence?

## **Method Overriding**

- If child class defines method with same name and signature as method in parent class
- say child's version overrides parent's version in favor of its own

## **Method Overriding**

13

```
nublic class CokeMachine2
  private static int totalMachines = 0;
  public CokeMachine2(int n)
    numberOrcans - n;
System.out.println("Adding another machine to your empire with "
    totalMachines++;
  public static int getTotalMachines()
    return totalMachines;
```

# **Method Overriding**

```
public int getNumberOfCans()
 return numberOfCans:
 if (numberOfCans > 0)
    System.out.println(" cans remaining");
    System.out.println("Sold Out");
  System.out.println("Please don't hurt me...take all my money"):
```

## **Method Overriding**

```
public class CokeMachine2000 extends CokeMachine2
 nublic CokeMachine2000()
 public CokeMachine2000(int n)
   super(n);
 public void loadCoke(int n)
   numberOfCans = numberOfCans + n;
System.out.println("loading " + n + " cans");
 public void vandalize() // this overrides the vandalize method from parent
   System.out.println("Stop it! Never mind, here's my money");
```

# **Method Overriding** public class CokeMachineUA extends CokeMachine2000 public CokeMachineUA() super(n); public void vandalize() // this overrides the vandalize method from parent System.out.println("Eat lead and die, you slimy Pepsi drinker!!");

**Method Overriding** public class SimVend public static void main (String[] args) for (int i = 0; i < mymachines.length; i++) if (mymachines[i] != null) mymachines[i].vandalize(); > iava SimVend Adding another mechanism to your empire with 10 cans of Cake Adding another machine to your empire with 10 cans of Cake Adding another machine to your empire with 10 cans of Coke Adding another machine to your empire with 10 cans of Coke Please don't hurt me...take all my money.
Stop it! Never mind, here's my money.
Eat lead and die, you slimy Pepsi drinker! **Method Overriding** 

- If child class defines method with same name and signature as method in parent class
- say child's version overrides parent's version
- in favor of its own • reminder: signature is number, type, and order
- of parameters Writing our own tostring() method for class overrides existing, inherited tostring()
- method Where was it inherited from?

**Method Overriding** 

- Where was it inherited from?
  - All classes that aren't explicitly extended from a named class are by default extended from Object class
  - Object class includes a tostring() method

**Method Overloading and Overriding** 

• in any class can use same name for several different (but

methods must have different signatures so that compiler can tell

subclass has method with same signature as a method in the

method in derived class overrides method in superclass

Method overloading: "easy" polymorphism

■ Method overriding: "complicated" polymorphism

resolved at execution time, not compilation time

some call it true polymorphism

hopefully related) methods

which one is intended

so... class header

public class myClass

is actually same as

public class myClass extends Object

# **Overriding Variables**

■ You can, but you shouldn't

**Overriding Variables** 

- You can, but you shouldn't
- Possible for child class to declare variable with same name as variable inherited from parent class
  - one in child class is called shadow variable
- confuses everyone!
- Child class already can gain access to inherited variable with same name
  - there's no good reason to declare new variable with the same name

**Another View of Polymorphism** 

- From Just Java 2 by Peter van der Linden:
  - Polymorphism is a complicated name for a straightforward concept. It merely means using the same one name to refer to different methods. "Name reuse" would be a better
- Polymorphism made possible in Java through method overloading and method overriding
  - remember method overloading?

superclass

## **Objectives**

- Understanding when and how to use abstract
- Understanding tradeoffs between interfaces and inheritance

**A New Wrinkle**

- Expand vending machine empire to include French fry machines
- is a French fry machine a subclass of Coke Machine?

If We Have This Class Hierarchy...

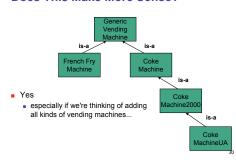

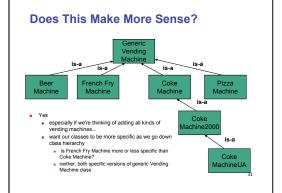

...Does This Make Sense?

**Does This Make More Sense?** 

## Inheritance Solution public class GenericVendingMachine

private int numberOfItems: private double cashIn: public GenericVendingMachine() numberOfItems = 0: public boolean vendItem( numberOfItems--; result = true; result = false: return result:

# **Inheritance Solution**

public void loadItems(int n) numberOfItems = n: public int getNumberOfItems() return numberOfTtems

# **Inheritance Solution**

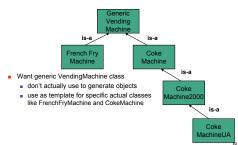

public class CokeMachine3 extends GenericVendingMachine public CokeMachine3() super(); public CokeMachine3(int n) this.loadItems(n); public void buyCoke() if (this.vendItem()) System.out.println("Have a nice frosty Coca-Cola!"); System.out.println(this.getNumberOfItems() + " cans of Coke remaining"); System.out.println("Sorry, sold out");

# **Inheritance Solution**

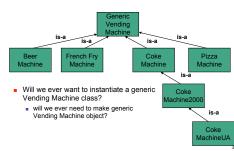

public void loadCoke(int n) this.loadItems(this.getNumberOfItems() + n); 

Inheritance Solution

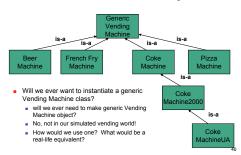

public class CokeMachine2000 extends CokeMachine3 public CokeMachine2000() super(): public CokeMachine2000(int n) this.loadItems(n); public void loadCoke(int n) super.loadCoke(n);
System.out.println("Loading in the new millennium!"); **Inheritance From Generic Objects** 

**Inheritance From Generic Objects** 

**Inheritance From Generic Objects** 

## **Inheritance From Generic Objects**

- Introduced CokeMachineUA to combat vandalism and theft
- Could just add vandalize() methods to CM, CM2000, CMUA
- but we want to ensure that all Vending Machines have vandalize() methods
- want all of them to be different
- if put into base class at top, easy to have them identical
- no way to force method overriding

**Abstract Classes** 

- Abstract class: not completely implemented
- Usually contains one or more abstract methods
  - has no definition: specifies method that should be implemented by
  - just has header, does not provide actual implementation for that method
- Abstract class uses abstract methods to specify what interface to descendant classes must look like
- without providing implementation details for methods that make up Example: require that all subclasses of VendingMachine class
- implement vandalize() method
- method might differ greatly between one subclass and another
- use an abstract method

Abstract Classes

- Abstract classes serve as place holders in class hierarchy
- Abstract class typically used as partial description inherited by all its descendants
- Description insufficient to be useful by itself
- cannot instantiated if defined properly
- Descendent classes supply additional information so that instantiation is meaningful
- abstract class is generic concept in class hierarchy
- class becomes abstract by including the abstract modifier in

■ Use abstract class for generic template can use abstract methods

**Abstract Classes** 

- Making abstract method
- Use restricted word abstract in method header
- do not provide a method body
- just end method header with semicolon

**Abstract Methods and Abstract Classes** 

- What happens when we try to compile it all now?
- Java tells us that there's an abstract class we have to implement

Could put this CokeMachine class: public void vandalize() System.out.println("Take all my money, and have a Coke too");

  - Could put this CokeMachine class:

System.out.println("Take all my money, and have a Coke too"):

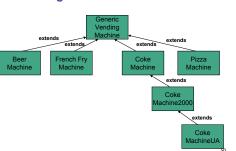

- Do we have to implement method in CokeMachine2000 and CokeMachineUA classes too?
  - Yes, if we want them to behave differently when they're vandalized original intent

public abstract class VendingMachine

**Vending Machine Class Revisited** private int numberOfItems: public VendingMachine() umberOfItems = 0; public boolean vend() ooolean result; numberOfItems--; result = true: } else result = false: return result; public abstract void vandalize()

## Interfaces vs. Abstract Classes

If we can have abstract class that contains only

abstract methods, why do we need interfaces?

### Interfaces vs. Abstract Classes

- If we can have abstract class that contains only abstract methods, why do we need interfaces?
  - Java does not support multiple inheritance: child classes inheriting attributes from multiple parent classes
  - other object-oriented languages do
     multiple inheritance can be good, but causes problems
    - what if child class inherits two different methods with same signature from two different parents?
    - which one should be used?

Interfaces vs. Abstract Classes

Another useful feature provided by interfaces:

• inheritance happens between classes that are

But classes can implement completely unrelated

Interfaces vs. Abstract Classes

- Java's formal interface provides some of the utility of multiple inheritance without the problems
- class can implement more than one interface
- can do this at same time it extends class
- Interface allows us to create classes that "inherit" features from multiple places

Interfaces vs. Abstract Classes

- Java's formal interface provides some of the utility of multiple inheritance without the problems
  - class can implement more than one interface
- can do this at same time it extends class
- Interface allows us to create classes that "inherit" features from multiple places
- Why is problem from previous slide solved?
  - might have multiple method headers with same signature

Interfaces vs. Abstract Classes

- Java's formal interface provides some of the utility of multiple inheritance without the problems
- class can implement more than one interface
   can do this at same time it extends class
- Interface allows us to create classes that "inherit" features from multiple places
- Why is problem from previous slide solved?
- might have multiple method headers with same signature
- but only one will have an actual definition
  - no ambiguity on which will be used
  - but still could be problem with different return types

and that can be useful

interfaces

Interfaces vs. Abstract Classes

- Another useful feature provided by interfaces:
  - inheritance happens between classes that are related
     But classes can implement completely unrelated interfaces
  - But classes can implement completely unrelated interfaces
     and that can be useful
- and that can be useful
- Example: implement interfaces for
  - computer, printer, cell phone, vending machine
  - create class for new interactive vending machines that:
  - vend Cokes, show annoying music videos, phone their owner when they're running low on product, and spit out coupons for free prizes

**How Interfaces Differ From Abstract Classes** 

- Abstract class is incomplete class that requires further specialization
  - interface is just specification or prescription for behavior

from Just Java 2 by Peter van der Linden

**How Interfaces Differ From Abstract Classes** 

- Abstract class is incomplete class that requires further specialization
- interface is just specification or prescription for behavior
- Inheritance implies specialization, interface does not
   interface iust implies "We need something that does 'foo' and
- here are ways that users should be able to call it."

from Just Java 2 by Peter van der Linden

Abstract class is incomplete class that requires further specialization

**How Interfaces Differ From Abstract Classes** 

- interface is just specification or prescription for behavior
- Inheritance implies specialization, interface does not
- interface just implies "We need something that does 'foo' and here are ways that users should be able to call it."
- Class can implement several interfaces at once
- but class can extend only one parent class

from Just Java 2 by Peter van der Linden

Interfaces vs. Abstract Classes: Bottom Line

- Use abstract class to initiate a hierarchy of more specialized classes
- Use interface to say, "I need to be able to call methods with these signatures in your class."
- Use an interface for some semblance of multiple inheritance

from Just Java 2 by Peter van der Linder

Interfaces vs. Abstract Classes

- Interface can only extend another interface
- cannot extend abstract class or "concrete" class
- Class can legally implement only some methods of interface if it's abstract class
  - then must be further extended through inheritance before can be instantiated

from Just Java 2 by Peter van der Linden

Who Can Do What?

- Interface can be implemented only by class or abstract class
   Interface can be extended only by another interface
- Class can be extended only by class or abstract class
- Abstract class can be extended only by class or abstract
- Only classes can be instantiated as objects
- Interfaces are not classes and cannot be instantiated
- Abstract classes may have undefined methods and cannot be instantiated
