CPSC 213

Introduction to Computer Systems

Unit 1b

Static Scalars and Arrays

Reading for Next 3 Lectures

- Companion
    - 2.4.1-2.4.3
- Textbook
    - Array Allocation and Access
    - 3.8

The Big Picture

- Build machine model of execution
    - for Java and C programs
    - by examining language features
    - and deciding how they are implemented by the machine
- What is required
    - design an ISA into which programs can be compiled
    - implement the ISA in the hardware simulator
- Our approach
    - examine code snippets that exemplify each language feature in turn
    - look at Java and C, pausing to dig deeper when C is different from Java
    - design and implement ISA as needed
- The simulator is an important tool
    - machine execution is hard to visualize without it
    - this visualization is really our WHOLE POINT here

Design Plan

Examine Java and C Bit by Bit

- Reading writing and arithmetic on Variables
    - static base types (e.g., int, char)
    - static and dynamic arrays of base types
    - dynamically allocated objects and object references
    - object instance variables
    - procedure locals and arguments
- Control flow
    - static intra-procedure control flow (e.g., if, for, while)
    - static procedure calls
    - dynamic control flow and polymorphic dispatch

Design Tasks

- Design Instructions for SM213 ISA
    - design instructions necessary to implement the languages
    - keep hardware simple/fast by adding as few/simple instructions possible
- Develop Compilation Strategy
    - determine how compiler will compile each language feature it sees
    - which instructions will it use?
    - in what order?
    - what can compiler compute statically?
- Consider Static and Dynamic Phases of Computation
    - the static phase of computation (compilation) happens just once
    - the dynamic phase (running the program) happens many times
    - thus anything the compiler computes, saves execution time later

The Simple Machine (SM213) ISA

- Architecture

Register File	8, 32-bit general purpose registers
CPU	one cycle per instruction (fetch + execute)
Main Memory	byte addressed, Big Endian integers

- Instruction Format
    - 2 or 6 byte instructions (each character is a hexit)
        - **x-01**, **xx-01**, **x0vv** or **x-01 vvvvvvvv**
    - where
        - **x** is *opcode* (unique identifier for this instruction)
        - **-** means unused
        - **0** and **1** are operands
        - **vv vvvvvvvv** are immediate / constant values

Machine and Assembly Syntax

- Machine code
    - [addr:] x-01 [vvvvvvvv]

addr:	sets starting address for subsequent instructions
x-01	hex value of instruction with opcode x and operands 0 and 1
vvvvvvvv	hex value of optional extended value part instruction

- Assembly code
    - ([label:] [instruction | directive] [# comment] |)*
        - directive :: (.pos number) | (.long number)
        - instruction :: opcode operand+
        - operand :: $literal | reg | offset (reg) | (reg,reg,4)
        - reg :: r 0..7
        - literal :: number
        - offset :: number
        - number :: decimal | 0x hex

Register Transfer Language (RTL)

- Goal
    - a simple, convenient pseudo language to describe instruction semantics
    - easy to read and write, directly translated to machine steps
- Syntax
    - each line is of the form LHS ← RHS
    - LHS is memory or register specification
    - RHS is constant, memory, or arithmetic expression on two registers
- Register and Memory are treated as arrays
    - m[a] is memory location at address a
    - r[i] is register number i
- For example
    - r[0] ← 10
    - r[1] ← m[r[0]]
    - r[2] ← r[0] + r[1]

Static Variables of Built-In Types

Static Variables, Built-In Types (S1-global-static)

- Java
    - static data members are allocated to a class, not an object
    - they can store built-in scalar types or references to arrays or objects (references later)

```
public class Foo {
  static int   a;
  static int[] b;   // array is not static, so skip for now

  public void foo () {
    a = 0;
  }}
```

- C
    - global variables and any other variable declared static
    - they can be static scalars, arrays or structs or pointers (pointers later)

```
int a;
int b[10];

void foo () {
  a    = 0;
  b[a] = a;
}
```

Static Variable Allocation

```
int a;
int b[10];

void foo () {
  a    = 0;
  b[a] = a;
}
```

```
int a;
int b[10];
```

Static Memory Layout

```
0x1000: value of a
0x2000: value of b[0]
0x2004: value of b[1]
...
0x2020: value of b[9]
```

- Allocation is
    - assigning a memory location to store variable's value
    - assigning the variable an address (its name for reading and writing)
- Key observation
    - global/static variables can exist before program starts and live until after it finishes
- Static vs dynamic computation
    - compiler allocates variables, giving them a constant address
    - no dynamic computation required to allocate the variables, they just exist

Static Variable Access (scalars)

```
int a;
int b[10];

void foo () {
  a    = 0;
  b[a] = a;
}
```

```
a = 0;
```

```
b[a] = a;
```

Static Memory Layout

```
0x1000: value of a
0x2000: value of b[0]
0x2004: value of b[1]
...
0x2020: value of b[9]
```

- Key Observation
    - address of **a**, **b[0]**, **b[1]**, **b[2]**, ... are constants known to the compiler
- Use RTL to specify instructions needed for **a = 0**

Generalizing

* What if it's a = a + 2? or a = b? or a = foo ()?

* What about reading the value of a?

Static Variable Access (static arrays)

```
int a;
int b[10];

void foo () {
  a    = 0;
  b[a] = a;
}
```

```
a = 0;
```

```
b[a] = a;
```

Static Memory Layout

```
0x1000: value of a
0x2000: value of b[0]
0x2004: value of b[1]
...
0x2020: value of b[9]
```

- Key Observation
    - compiler does not know address of **b[a]**
        - unless it can knows the value of a statically, which it could here by looking at a=0, but not in general
- Array access is computed from base and index
    - address of element is *base* plus *offset*; *offset* is *index* times element size
    - the base address (0x2000) and element size (4) are static, the index is dynamic
- Use RTL to specify instructions for **b[a] = a**, not knowing **a**?

Designing ISA for Static Variables

- Requirements for scalars `a = 0;`
    - load constant into register
        - r[x] ← v
    - store value in register into memory at constant address
        - m[0x1000] ← r[x]
    - load value in memory at constant address into a register
        - r[x] ← m[0x1000]
- Additional requirements for arrays `b[a] = a;`
    - store value in register into memory at address in register*4 plus constant
        - m[0x2000+r[x]*4] ← r[y]
    - load value in memory at address in register*4 plus constant into register
        - r[y] ← m[0x2000+r[x]*4]
- Generalizing and simplifying we get
    - r[x] ← constant
    - m[r[x]] ← r[y] and r[y] ← m[r[x]]
    - m[r[x] + r[y]*4] ← r[z] and r[z] ← m[r[x] + r[y]*4]

- The compiler's semantic translation
    - it uses these instructions to compile the program snippet

```
int a;
int b[10];

void foo () {
  a = 0;
  b[a] = a;
}
```

```
r[0]          ← 0
r[1]          ← 0x1000
m[r[1]]        ← r[0]

r[2]          ← m[r[1]]
r[3]          ← 0x2000
m[r[3]+r[2]*4] ← r[2]
```

- ISA Specification for these 5 instructions

Name	Semantics	Assembly	Machine
load immediate	r[d] ← v	ld $v, rd	0d-- vvvvvvvv
load base+offset	r[d] ← m[r[s]]	ld ?(rs), rd	1?sd
load indexed	r[d] ← m[r[s]+4*r[i]]	ld (rs,ri,4), rd	2sid
store base+offset	m[r[d]] ← r[s]	st rs, ?(rd)	3s?d
store indexed	m[r[d]+4*r[i]] ← r[s]	st rs, (rd,ri,4)	4sdi

- The compiler's assembly translation

```
int a;
int b[10];

void foo () {
  a = 0;
  b[a] = a;
}
```

```
r[0]           ← 0
r[1]           ← 0x1000
m[r[1]]          ← r[0]

r[2]           ← m[r[1]]
r[3]           ← 0x2000
m[r[3]+r[2]*4] ← r[2]
```

```
int a;
int b[10];

void foo () {
  a = 0;
  b[a] = a;
}
```

```
ld $0, r0
ld $0x1000, r1
st r0, (r1)

ld (r1), r2
ld $0x2000, r3
st r2, (r3,r2,4)
```

- If a human wrote this assembly
  - list static allocations, use labels for addresses, add comments

```
int a;
int b[10];

void foo () {
  a = 0;
  b[a] = a;
}
```

```
ld $0, r0        # r0 = 0
ld $a_data, r1   # r1 = address of a
st r0, (r1)      # a = 0

ld (r1), r2      # r2 = a
ld $b_data, r3   # r3 = address of b
st r2, (r3,r2,4) # b[a] = a

.pos 0x1000
a_data:
.long 0          # the variable a

.pos 0x2000
b_data:
.long 0          # the variable b[0]
.long 0          # the variable b[1]
...
.long 0          # the variable b[9]
```

Addressing Modes

- In these instructions

Name	Semantics	Assembly	Machine
load immediate	r[d] ← v	ld $v, rd	0d-- vvvvvvvv
load base+offset	r[d] ← m[?+r[s]]	ld ?(rs), rd	1?sd
load indexed	r[d] ← m[r[s]+4*r[i]]	ld (rs,ri,4), rd	2sid
store base+offset	m[?+r[d]] ← r[s]	st rs, ?(rd)	3s?d
store indexed	m[r[d]+4*r[i]] ← r[s]	st rs, (rd,ri,4)	4sdi

- We have specified 4 *addressing modes* for operands

immediate	constant value stored in instruction
register	operand is register number, register stores value
base+offset	operand is register number, register stores memory address of value (+ offset)
indexed	two register-number operands store base memory address and index of value

---

Basic Arithmetic, Shifting, NOP and Halt

- Arithmetic

Name	Semantics	Assembly	Machine
register move	r[d] ← r[s]	mov rs, rd	60sd
add	r[d] ← r[d] + r[s]	add rs, rd	61sd
and	r[d] ← r[d] & r[s]	and rs, rd	62sd
inc	r[d] ← r[d] + 1	inc rd	63-d
inc address	r[d] ← r[d] + 4	inca rd	64-d
dec	r[d] ← r[d] – 1	dec rd	65-d
dec address	r[d] ← r[d] – 4	deca rd	66-d
not	r[d] ← ~ r[d]	not rd	67-d

- Shifting, NOP and Halt

Name	Semantics	Assembly	Machine
shift left	r[d] ← r[d] << S = s	shl rd, s	7dSS
shift right	r[d] ← r[d] << S = -s	shr rd, s	
halt	*halt machine*	halt	f0--
nop	*do nothing*	nop	ff--

Global Dynamic Array

Global Dynamic Array

- Java
  - array variable stores reference to array allocated dynamically with **new** statement

```
public class Foo {
  static int a;
  static int b[] = new int[10];

  void foo () {
    b[a]=a;
  }}
```

- C
  - array variables can store static arrays or pointers to arrays allocated dynamically with call to **malloc** library procedure

```
int  a;
int* b;

void foo ()
  b = (int*) malloc (10*sizeof(int));
  b[a] = a;
}
```

malloc does not assign a type

# of bytes to allocate

How C Arrays are Different from Java

- Terminology
  - use the term ***pointer*** instead of ***reference***; they mean the same thing
- Declaration
  - the type is a pointer to the type of its elements, indicated with a *
- Allocation
  - malloc allocates a block of bytes; no type; no constructor
- Type Safety
  - any pointer can be type cast to any pointer type
- Bounds checking
  - C performs no array bounds checking
  - out-of-bounds access manipulates memory that is not part of array
  - this is the major source of virus vulnerabilities in the world today

Question: Can array bounds checking be perform statically?
* what does this say about a tradeoff that Java and C take differently?

Static vs Dynamic Arrays

- Declared and allocated differently, but accessed the same

```
int a;
int b[10];

void foo () {
  b[a] = a;
}
```

```
int  a;
int* b;

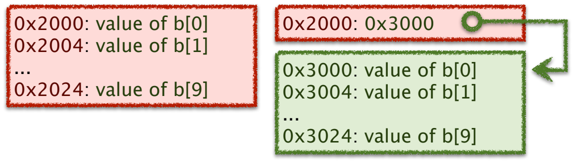
void foo () {
  b = (int*) malloc (10*sizeof(int));
  b[a] = a;
}
```

- Static allocation
  - for static arrays, the compiler allocates the array
  - for dynamic arrays, the compiler allocates a pointer

0x2000: value of b[0]
0x2004: value of b[1]
...
0x2024: value of b[9]

0x2000: value of b

- Then when the program runs
  - the dynamic array is allocated by a call to malloc, say at address 0x3000
  - the value of variable b is set to the memory address of this array



0x2000: value of b[0]
0x2004: value of b[1]
...
0x2024: value of b[9]

0x2000: 0x3000

0x3000: value of b[0]
0x3004: value of b[1]
...
0x3024: value of b[9]

- Generating code to access the array
  - for the dynamic array, the compiler generates an additional load for b

```
r[0]           ← 0x1000
r[1]           ← m[r[0]]
r[2]           ← 0x2000
m[r[2]+r[1]*4] ← r[1]
```

```
r[0]           ← 0x1000
r[1]           ← m[r[0]]
r[2]           ← 0x2000
r[3]           ← m[r[2]]
m[r[3]+r[1]*4] ← r[1]
```

load a

load b
b[a]=a

- In assembly language

Static Array

```
ld $a_data, r0   # r0 = address of a
ld (r0), r1      # r1 = a
ld $b_data, r2   # r2 = address of b
st r1, (r2,r1,4) # b[a] = a

.pos 0x1000
a_data:
.long 0          # the variable a

.pos 0x2000
b_data:
.long 0          # the variable b[0]
.long 0          # the variable b[1]
...
.long 0          # the variable b[9]
```

Dynamic Array

```
ld $a_data, r0   # r0 = address of a
ld (r0), r1      # r1 = a
ld $b_data, r2   # r2 = address of b
ld (r2), r3      # r3 = b
st r1, (r3,r1,4) # b[a] = a

.pos 0x1000
a_data:
.long 0          # the variable a

.pos 0x2000
b_data:
.long 0          # the b
```

- Comparing static and dynamic arrays
  - what is the benefit of static arrays?
  - what is the benefit of dynamic arrays?

Pointers in C

C and Java Arrays and Pointers

- In both languages
  - an array is a list of items of the same type
  - array elements are named by non-negative integers start with 0
  - syntax for accessing element i of array b is b[i]
- In Java
  - variable a stores a pointer to the array
  - b[x] = 0 means *m[m[b] + x * sizeof(array-element)] ← 0*
- In C
  - variable a can store a pointer to the array or the array itself
  - b[x] = 0 means *m[b + x * sizeof(array-element)] ← 0*
    or *m[**m[b]** + x * sizeof(array-element)] ← 0*
  - dynamic arrays are just like all other pointers
    - stored in TYPE*
    - access with either a[x] or *(a+x)

Example

- The following two C programs are identical

```
int *a;
a[4] = 5;
```

```
int *a;
*(a+4) = 5;
```

- For array access, the compiler would generate this code

```
r[0]           ← a
r[1]           ← 4
r[2]           ← 5
m[r[0]+4*r[1]] ← r[2]
```

```
ld $a, r0
ld $4, r1
ld $5, r2
st r2, (r0,r1,4)
```

  - multiplying the index 4 by 4 (size of integer) to compute the array offset
- So, what does this tell you about pointer arithmetic in C?

Adding X to a pointer of type Y*, adds X * sizeof(Y) to the pointer's memory-address value.

Pointer Arithmetic in C

- Its purpose
  - an alternative way to access dynamic arrays to the a[i]
- Adding or subtracting an integer *index* to a pointer
  - results in a new pointer of the same type
  - value of the pointer is offset by index times size of pointer's referent
  - for example
    - adding 3 to an int* yields a pointer value 12 larger than the original
- Subtracting two pointers of the same type
  - results in an integer
  - gives number of referent-type elements between the two pointers
  - for example
    - (& a[7]) – (& a[2])) == 5 == (a+7) – (a+2)
- other operators
  - **&** X the address of X
  - * X the value X points to

Question (from S3-C-pointer-math.c)

```
int *c;

void foo () {
  // ...
  c = (int *) malloc (10*sizeof(int));
  // ...
  c = &c[3];
  *c = *&c[3];
  // ...
}
```

- What is the equivalent Java statement to
  - [b] c[0] = c[3];
  - [g] c[3] = c[6];
  - [r] there is no typesafe equivalent
  - [y] not valid, because you can't take the address of a static in Java

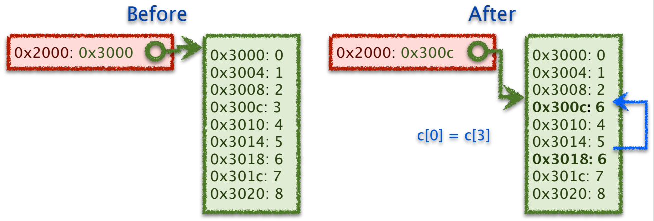
---

Looking more closely

```
c = &c[3];
*c = *&c[3];
```

```
r[0]    ← 0x2000          # r[0] = &c
r[1]    ← m[r[0]]         # r[1] = c
r[2]    ← 12              # r[2] = 3 * sizeof(int)
r[2]    ← r[2]+r[1]       # r[2] = c + 3
m[r[0]] ← r[2]            # c    = c + 3

r[3]    ← 3               # r[3] = 3
r[4]    ← m[r[2]+4*r[3]]  # r[4] = c[3]
m[r[2]] ← r[4]            # c[0] = c[3]
```



Before

0x2000: 0x3000

0x3000: 0
0x3004: 1
0x3008: 2
0x300c: 3
0x3010: 4
0x3014: 5
0x3018: 6
0x301c: 7
0x3020: 8

After

0x2000: 0x300c

0x3000: 0
0x3004: 1
0x3008: 2
0x300c: 6
0x3010: 4
0x3014: 5
0x3018: 6
0x301c: 7
0x3020: 8

c[0] = c[3]

- And in assembly language

```
r[0]    ← 0x2000        # r[0] = &c
r[1]    ← m[r[0]]       # r[1] = c
r[2]    ← 12            # r[2] = 3 * sizeof(int)
r[2]    ← r[2]+r[1]     # r[2] = c + 3
m[r[0]] ← r[2]          # c    = c + 3

r[3]    ← 3             # r[3] = 3
r[4]    ← m[r[2]+4*r[3]] # r[4] = c[3]
m[r[2]] ← r[4]          # c[0] = c[3]
```

```
ld $0x2000, r0          # r0 = &c
ld (r0), r1             # r1 = c
ld $12, r2              # r2 = 3*sizeof(int)
add r1, r2              # r2 = c+3
st r2, (r0)             # c  = c+3

ld $3, r3               # r3   = 3
ld (r2,r3,4), r4        # r4   = c[3]
st r4, (r2)             # c[0] = c[3]
```

Summary: Static Scalar and Array Variables

- Static variables
  - the compiler knows the address (memory location) of variable
- Static scalars and arrays
  - the compiler knows the address of the scalar value or array
- Dynamic arrays
  - the compiler does not know the address the array
- What C does that Java doesn’t
  - static arrays
  - arrays can be accessed using pointer dereferencing operator
  - arithmetic on pointers
- What Java does that C doesn’t
  - typesafe dynamic allocation
  - automatic array-bounds checking
