Virtual Processors

Readings for These Next Four Lectures

Text

Concurrent Programming With Threads

- 2nd: 12.3
- 1st: 13.3

The Virtual Processor

Originated with Edsger Dijkstra in the THE Operating System

• in The Structure of the "THE" Multiprogramming System, 1968

"I had had extensive experience (dating back to 1958) in making basic software dealing with real-time interrupts, and I knew by bitter experience that as a result of the irreproducibility of the interrupt moments a program error could present itself misleadingly like an occasional machine malfunctioning. As a result **I was terribly afraid**. Having fears regarding the possibility of debugging, we decided to be as careful as possible and, prevention being better than cure, to try to prevent nasty bugs from entering the construction.

This decision, inspired by fear, is at the bottom of what I regard as the group's main contribution to the art of system design."

The Process (what we now call a Thread)

- a single thread of synchronous execution of a program
 - the illusion of a single system such as the Simple Machine
- can be stopped and restarted
 - stopped when waiting for an event (e.g., completion of an I/O operation)
 - restarted with the event fires
- can co-exist with other processes sharing a single hardware processor
 - a scheduler multiplexes processes over processor
 - synchronization primitives are used to ensure mutual exclusion and for waiting and signalling

Thread

An abstraction for execution

- looks to programmer like a sequential flow of execution, a private CPU
- it can be stopped and started, it is sometimes running and sometimes not
- the physical CPU thus now multiplexes multiple threads at different times

Creating and starting a thread

- like an asynchronous procedure call
- starts a new thread of control to execute a procedure

Stopping and re-starting a thread

- stopping a thread is called blocking
- a blocked thread can be re-started (i.e., unblocked)

Joining with a thread

- blocks the calling thread until a target thread completes
- returns the return value of the target-thread's starting procedure
- turns thread create back into a synchronous procedure call

ioin

bat

Threads in Java

- Create a procedure that can be executed by a thread
 - build a class that implements the Runnable interface

```
class ZotRunnable implements Runnable {
    Integer result, arg;
    ZotRunnable (Integer anArg) {
        arg = arg;
    }
    public void run () {
        result = zot (anArg);
    }
}
```

Create a thread to execute the procedure and start it

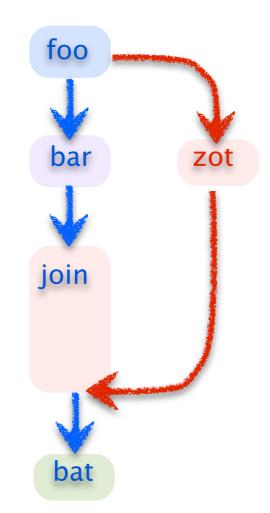

```
ZotRunnable zot = new ZotRunnable (0);
Thread t = new Thread (zot);
t.start ();
```

Later join with thread to get zot's return value

```
Integer result;
try {
  t.join ();
  result = zot.result;
} catch (InterruptedException ie) {
  result = null;
}
```

So that the entire calling sequence is

```
foo ();
ZotRunnable zot = new ZotRunnable (0);
Thread t = new Thread (zot);
t.start ();
bar ();
Integer result = null;
try {
   t.join ();
   result = zot.result;
} catch (InterruptedException ie) {
}
bat ();
```

Executor Services in Java

Create an Executor Service

• to manage asynchronous calls in a pool of threads (here limited to 2)

ExecutorService ex = new ScheduledThreadPoolExecutor (2);

Create a procedure that can be submitted to this Service

build a class that implements the Callable interface

```
class ZotCallable implements Callable <Integer > {
    Integer arg;
    ZotCallable (Integer anArg) {
        arg = anArg;
    }
    public Integer call () {
        return zot (arg);
    }
}
```

Schedule execution of the procedure

- declare a Future variable to store the procedure's result
- submit procedure's callable object to the Executor Service

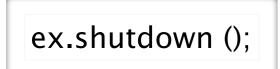

Future < Integer > resultFuture = ex.submit (new ZotCallable (0));

Then later get value of result future, blocking if necessary

```
Integer result = null;
try {
  result = resultFuture.get ();
} catch (InterruptedException ie) {
} catch (ExecutionException ee) {}
```

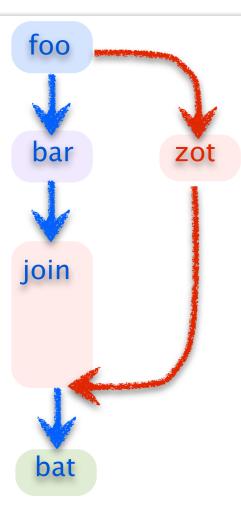

Shutdown Executor Service before program terminates

return from main does terminate the program until Executor is shutdown

So that the entire calling sequence is

```
ExecutorService ex = new ScheduledThreadPoolExecutor (2);
foo ();
Future<Integer> resultFuture = ex.submit (new ZotCallable (0));
bar ();
Integer result = null;
try {
 result = resultFuture.get ();
} catch (InterruptedException ie) {
} catch (ExecutionException ee) {}
bat ();
ex.shutdown ();
```

Comparing Java's Alternatives

Focusing on asynchronous call

```
ZotRunnable zot = new ZotRunnable (0);
Thread t = new Thread (zot);
t.start ();
Integer result = null;
try {
   t.join ();
   result = zot.result;
} catch (InterruptedException ie) {
```

```
Future < Integer > resultFuture = ex.submit (new ZotCallable (0));
Integer result = null;
try {
  result = resultFuture.get ();
} catch (InterruptedException ie) {
} catch (ExecutionException ee) {} // if zot() threw an exception
```

Advantages of Executor Service

- better management of result returned or exception thrown by asynchronous call
- precise thread management abstracted from application code

UThread: A Simple Thread System for C

The UThread Interface file (uthread.h)

```
struct uthread_TCB;
typedef struct uthread_TCB uthread_t;
void uthread_init ();
uthread_t* uthread_create (void* (*start_proc)(void*), void* start_arg);
void uthread_yield ();
void uthread_join (uthread_t* thread);
void uthread_detach (uthread_t* thread);
uthread_t* uthread_self ();
```

Explained

uthread_t	is the datatype of a thread control block
 uthread_init 	is called once to initialize the thread system
 uthread_create 	create and start a thread to run specified procedure
 uthread_yield 	temporarily stop current thread if other threads waiting
 uthread_join 	join calling thread with specified other thread
 uthread_detach 	indicate no thread will join specified thread
 uthread_self 	a pointer to the TCB of the current thread

Example Program using UThreads

```
void ping () {
    int i;
    for (i=0; i<100; i++) {
        printf ("ping %d\n",i); fflush (stdout);
        uthread_yield ();
    }</pre>
```

```
void pong () {
    int i;
    for (i=0; i<100; i++) {
        printf ("pong %d\n",i); fflush (stdout);
        uthread_yield ();
    }
}</pre>
```

```
void ping_pong () {
   uthread_create (ping, 0);
   uthread_create (pong, 0);
   while (1)
     uthread_yield ();
}
```

Implement Threads: Some Questions

The key new thing is blocking and unblocking

- what does it mean to stop a thread?
- what happens to the thread?
- what happens to the physical processor?

What data structures do we need

What basic operations are required

Implementing UThreads: Data Structures

Thread State

- running: register file and runtime stack
- stopped: Thread Control Block and runtime stack

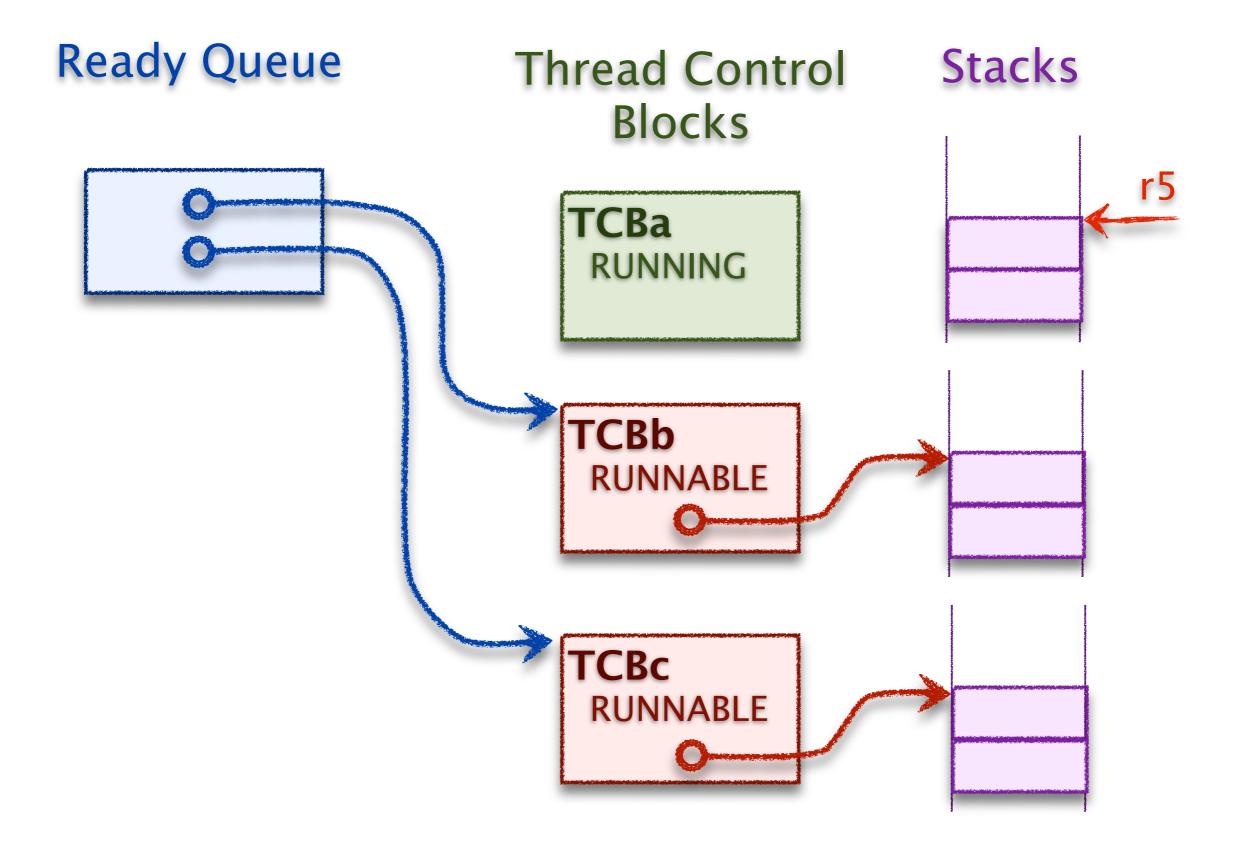

Thread-Control Block (TCB)

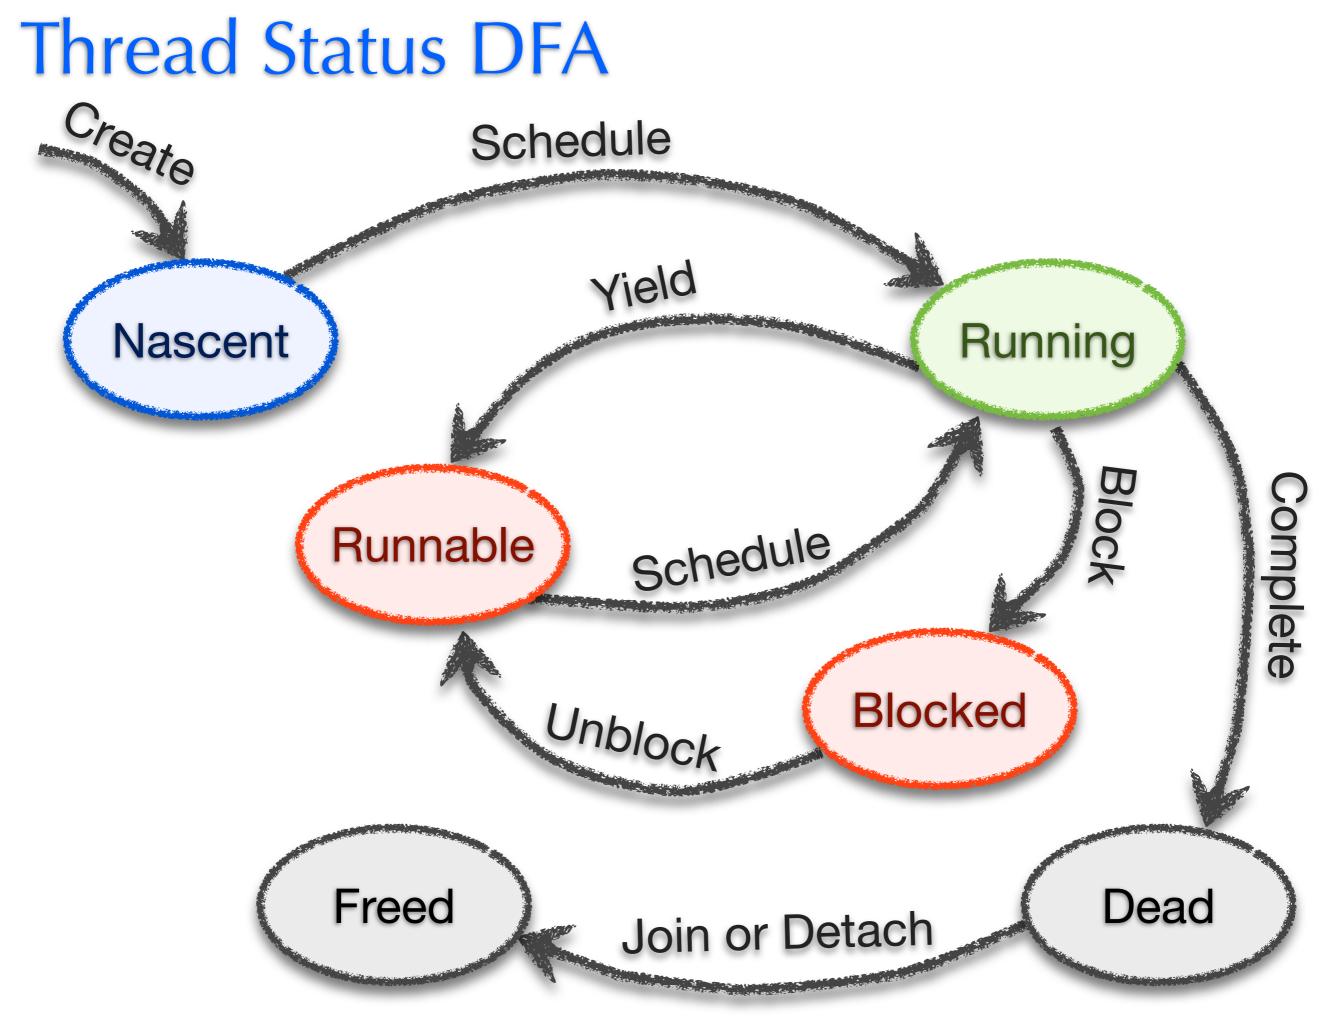

- thread status: (NASCENT, RUNNING, RUNNABLE, BLOCKED, or DEAD)
- pointers to thread's stack base and top of its stack
- scheduling parameters such as priority, quantum, pre-emptability etc.

Ready Queue

- list of TCB's of all RUNNABLE threads
- One or more Blocked Queues
 - list of TCB's of BLOCKED threads

Thread Data Structure Diagram

Implementing Threads: Thread Switch

Goal

- implement a procedure switch (T_a , T_b) that stops T_a and starts T_b
- T_a calls switch, but it returns to T_b
- example ...

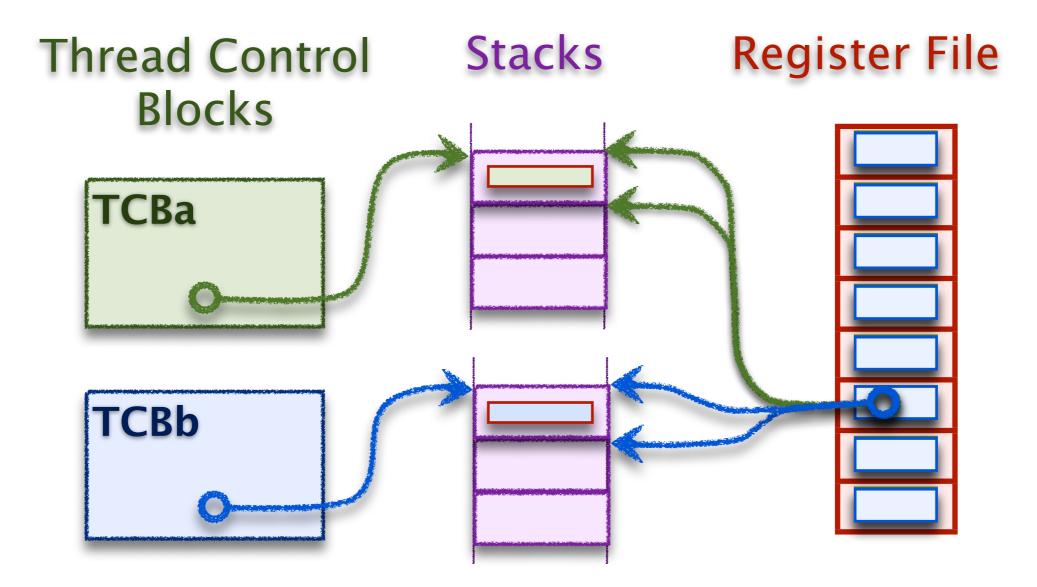

Requires

- \bullet saving T_a 's processor state and setting processor state to T_b 's saved state
- state is just registers and registers can be saved and restored to/from stack
- thread-control block has pointer to top of stack for each thread

Implementation

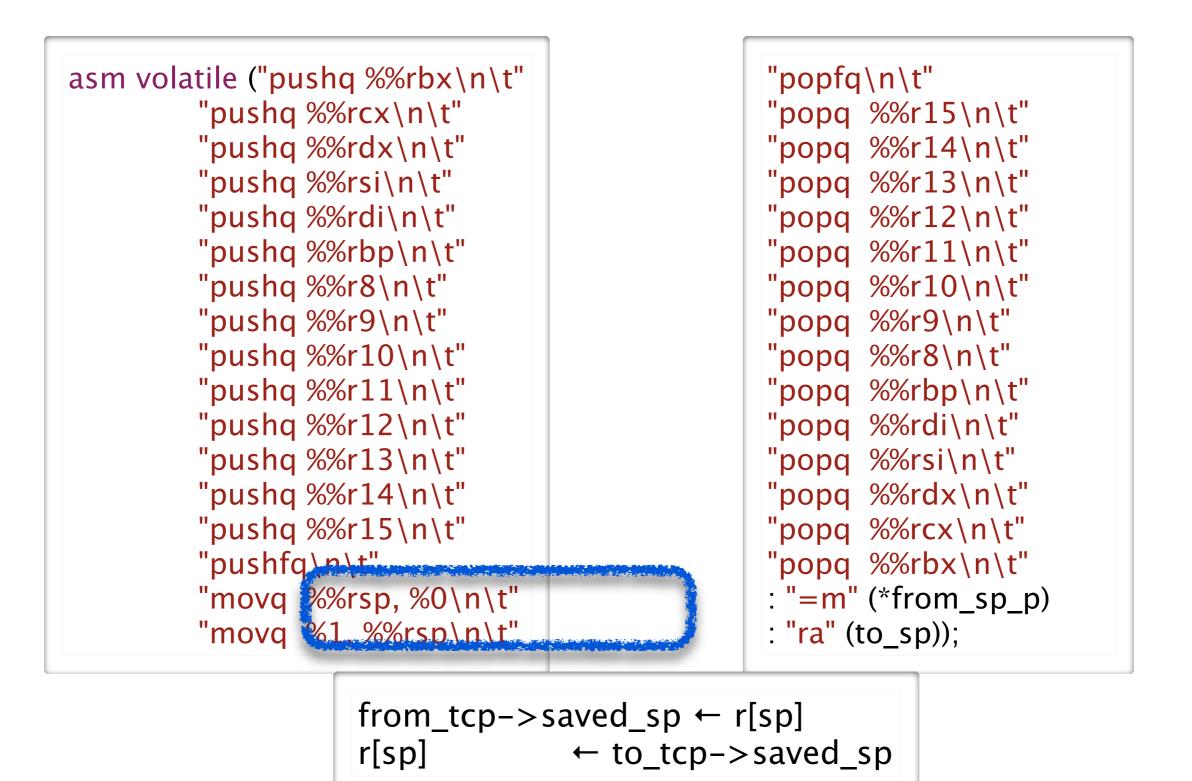

- save all registers to stack
- save stack pointer to Ta's TCB
- set stack pointer to stack pointer in Tb's TCB
- restore registers from stack

Thread Switch

- 1. Save all registers to A's stack
- 2. Save stack top in A's TCB
- 3. Restore B's stack top to stack-pointer register
- 4. Restore registers from B's stack

Example Code for Thread Switch

Implementing Thread Yield

Thread Yield

- gets next runnable thread from ready queue (if any)
- puts current thread on ready queue
- switches to next thread

Example Code

```
void uthread_yield () {
    uthread_t* to_thread = dequeue (&ready_queue);
    uthread_t* from_thread = uthread_cur_thread ();
    if (to_thread) {
        from_thread->state = TS_RUNABLE;
        enqueue (&ready_queue, from_thread);
        uthread_switch (to_thread);
    }
}
```

Multiple Processors

Processors are

- the physical / hardware resource that runs threads
- a system can have more than one

Uni-Processor System

- a single processor runs all threads
- no two threads run at the same time

Multi-Processor System

- multiple processors run the threads
- two threads can be running at the same time

More about this later, but we have a problem now ...

- how do we compute the value of cur_thread, the current thread's TCB?
- we need this to yield the thread, for example, to place it on ready queue
- but, can't use a global variable

Thread Private Data

Threads introduce need for another type of variable

- a thread-private variable is a global variable private to a thread
- like a local variable is private to a procedure activation

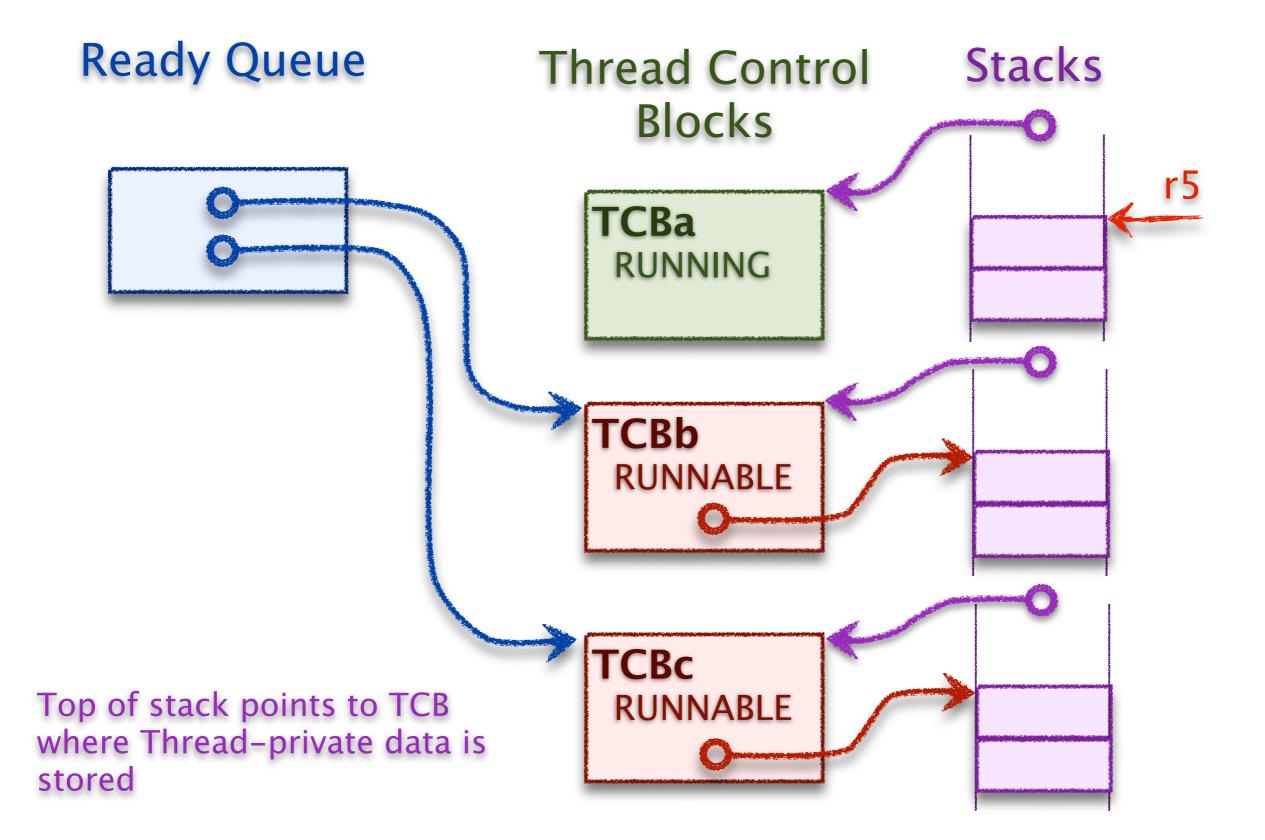

For example

- cur_thread, the address of the current thread's activation frame
- It's a global variable to thread, but every thread has its own copy

Implementing Thread Private Data

- store Thread-private data in TCB
- store pointer to TCB at top of every stack
- compute current stack top from stack pointer
 - require that stack top address is aligned to stack size
 - stack top = r5 & ~(Stack Size 1)

Thread Private Data

Thread Scheduling

Thread Scheduling is

- the process of deciding when threads should run
- when there are more runnable threads than processors
- involves a policy and a mechanism

Thread Scheduling Policy

is the set of rules that determines which threads should be running

Things you might consider when setting scheduling policy

- do some threads have higher priority than others?
- should threads get fair access to the processor?
- should threads be guaranteed to make progress?
- do some operations have deadlines?
- should one thread be able to pre-empt another?
- if threads can be pre-empted, are there times when this shouldn't happen?

Priority, Round Robin Scheduling Policy

Priority

- is a number assigned to each thread
- thread with highest priority goes first

When choosing the next thread to run

- run the highest priority runnable thread
- when threads are same priority, run thread that has waited the longest

Implementing Thread Mechanism

- organize Ready Queue as a priority queue
 - highest priority first
 - first-in-first out (FIFO) among equal-priority threads

Benefits

Drawbacks and mitigation

Preemption

Preemption occurs when

- a "yield" is forced upon the current running thread
- current thread is stopped to allow another thread to run

Priority-based preemption

- when a thread is made runnable (e.g., created or unblocked)
- if it is higher priority than current-running thread, it preempts that thread

Quantum-based preemption

- each thread is assigned a runtime "quantum"
- thread is preempted at the end of its quantum

How long should quantum be?

- disadvantage of too short?
- disadvantage of too long?
- typical value is around 100 ms
- How is quantum-based preemption implemented?

Implementing Quantum Preemption

Timer Device

- an I/O controller connected to a clock
- interrupts processor at regular intervals

Timer Interrupt Handler

- compares the running time of current thread to its quantum
- preempts it if quantum has expired

How is running thread preempted

Real-Time Scheduling

Problem with round-robin, preemptive, priority scheduling

- some applications require threads to run at a certain time or certain interval
- but, what does round-robin guarantee and not guarantee?

Real-time Scheduling

- hard realtime e.g., for controlling or monitoring devices
 - thread is guaranteed a regular timeslot and is given a time budget
 - thread can not exceed its time budget
 - thread will not be "admitted" to the run in the first place, unless its schedule can be guaranteed
- soft realtime e.g., for media streaming
 - option 1: over-provision and use round-robin
 - option 2: thread expresses its scheduling needs, scheduler tries its best, but no guarantee

Summary

User-Level Threads

- notice that we haven't talked about the OS yet (we will soon)
- everything we've talked about can be implemented in an application
- the difference between OS and application is processor privilege level
 - OS is "kernel"-level
 - Applications are "user"-level
- and so, what we are talking about are called User-Level Threads

Thread State

- when running: stack and machine registers (register file etc.)
- when stopped: Thread Control Block stores stack pointer, stack stores state

Round-Robin, Preemptive, Priority Thread Scheduling

- lower priority thread preempted by higher
- thread preempted when its quantum expires
- equal-priority threads get fair share of processor, in round-robin fashion
