

CSP Planning; Logic Intro

CPSC 322 Lecture 17

February 20, 2006

Textbook §11.2 and §4.0 – 4.2

Lecture Overview

Recap

CSP Planning

Logic Intro

Forward Planning

Idea: search in the state-space graph.

- ▶ The nodes represent the states
- ▶ The arcs correspond to the actions: The arcs from a state s represent all of the actions that are legal in state s .
- ▶ A plan is a path from the state representing the initial state to a state that satisfies the goal.

Regression Planning

Idea: search backwards from the goal description: nodes correspond to subgoals, and arcs to actions.

- ▶ **Nodes** are propositions: partial assignments to state variables
- ▶ **Start node:** the goal condition
- ▶ **Arcs** correspond to actions
- ▶ A node that **neighbours** N via arc A is a variable assignment that specifies what must be true immediately before A so that N is true immediately after.
- ▶ The **goal test** is true if N is a proposition that is true of the initial state.

Regression Planning: defining nodes and arcs

- ▶ A **node** N is a partial assignment of values to variables:

$$[X_1 = v_1, \dots, X_n = v_n]$$

- ▶ An **action** which can be taken to this node is one that achieves one of the $X_i = v_i$, and does not achieve any $X_j = v_j$ where v'_j is different from v_j .
- ▶ Any node that **neighbours** N via arc A must contain:
 - ▶ The prerequisites of action A
 - ▶ All of the elements of N that were not achieved by A N must be consistent.

Recap

CSP Planning

Logic Intro

Planning as a CSP

- ▶ We can go forwards and backwards at the same time, if we set up a planning problem as a CSP
- ▶ To do this, we need to “unroll” the plan for a fixed number of steps
 - ▶ this is called the **horizon**
- ▶ To do this with a horizon of k :
 - ▶ construct a **variable for each feature at each time step** from 0 to k
 - ▶ construct a boolean **variable for each action at each time step** from 0 to $k - 1$.

CSP Planning: Constraints

As usual, we have to express the preconditions and effects of actions:

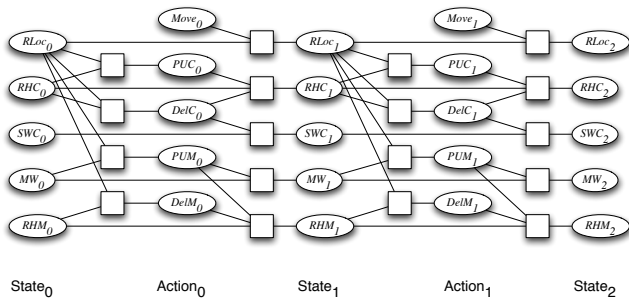

- ▶ **precondition constraints**
 - ▶ hold between state variables at time t and action variables at time t
 - ▶ specify when actions may be taken
- ▶ **effect constraints**
 - ▶ between state variables at time t , action variables at time t and state variables at time $t + 1$
 - ▶ explain how state variables at time $t + 1$ are affected by the action taken at time t
 - ▶ this includes both causal and frame axioms
 - ▶ basically, it goes back to the feature-centric representation we had before STRIPS
 - ▶ of course, solving the problem this way doesn't mean we can't *encode* the problem using STRIPS

CSP Planning: Constraints

Other constraints we must/may have:

- ▶ **initial state constraints** constrain the state variables at time 0
- ▶ **goal constraints** constrain the state variables at time k
- ▶ **action constraints**
 - ▶ specify which actions cannot occur simultaneously
 - ▶ note that without these constraints, there's nothing to stop the planner from deciding to take several actions simultaneously
 - ▶ when the order between several actions doesn't matter, this is a good thing
 - ▶ these are sometimes called mutual exclusion (mutex) constraints
- ▶ **state constraints**
 - ▶ hold between variables at the same time step
 - ▶ they can capture physical constraints of the system
 - ▶ they can encode maintenance goals

CSP Planning: Robot Example

Do you see why CSP planning is both forwards and backwards?

Recap

CSP Planning

Logic Intro

Logic: A more general framework for reasoning

- ▶ Let's now think about how to represent a world about which we have only partial (but certain) information
- ▶ Our tool: **propositional logic**
- ▶ General problem:
 - ▶ tell the computer how the world works
 - ▶ tell the computer some facts about the world
 - ▶ ask a yes/no question about whether other facts must be true

Why Propositions?

We'll be looking at problems that could still be represented using CSPs. Why use propositional logic?

- ▶ Specifying logical formulae is often **more natural** than filling in tables (i.e., arbitrary constraints)
- ▶ It is **easier to check and debug** formulae than tables
- ▶ We can exploit the **Boolean** nature for efficient reasoning
- ▶ We need a language for **asking queries** that may be more complicated than asking for the value of one variable
- ▶ It is easy to **incrementally add** formulae
- ▶ It can be extended to **infinitely many variables** (using logical quantification)
- ▶ This is a starting point for **more complex logics** (e.g., first-order logic) that go beyond CSPs.

Representation and Reasoning System

A Representation and Reasoning System (RRS) is made up of:

- ▶ **syntax**: specifies the symbols used, and how they can be combined to form legal sentences
- ▶ **semantics**: specifies the meaning of the symbols
- ▶ **reasoning theory or proof procedure**: a (possibly nondeterministic) specification of how an answer can be produced.
