

Regression Planning

CPSC 322 Lecture 17

February 14, 2007

Textbook §11.2 and §4.0 – 4.2

Lecture Overview

- 1 Recap
- 2 Regression Planning

Forward Planning

Idea: search in the state-space graph.

- The nodes represent the states
- The arcs correspond to the actions: The arcs from a state s represent all of the actions that are legal in state s .
- A plan is a path from the state representing the initial state to a state that satisfies the goal.

Regression Planning

Idea: search backwards from the goal description: nodes correspond to subgoals, and arcs to actions.

- **Nodes** are propositions: partial assignments to state variables
- **Start node:** the goal condition
- **Arcs** correspond to actions
- A node that **neighbours** N via arc A is a variable assignment that specifies what must be true immediately before A so that N is true immediately after.
- The **goal test** is true if N is a proposition that is true of the initial state.

Comparing forward and regression planners

- Which is more **efficient** depends on:
 - The branching factor
 - How good the heuristics are
- **Forward planning** is unconstrained by the goal (except as a source of heuristics).
- **Regression planning** is unconstrained by the initial state (except as a source of heuristics)

Lecture Overview

- 1 Recap
- 2 Regression Planning

Formalizing arcs using STRIPS notation

If we're currently at a node $[X_1 = v_1, \dots, X_n = v_n]$ then an arc labeled A exists to another node N if

- There exists some i for which $X_i = v_i$ is on the effects list of action A
- For all j , $X_j = v'_j$ is not on the effects list for A , where $v'_j \neq v_j$
- N is $preconditions(A) \cup \{X_k = v_k : X_k = v_k \notin effects(A)\}$ and N is consistent in that it does not assign multiple values to any one variable.

Regression example

Actions

mc: move clockwise

mac: move anticlockwise

nm: no move

puc: pick up coffee

dc: deliver coffee

pum: pick up mail

dm: deliver mail

Locations:

cs: coffee shop

off: office

lab: laboratory

mr: mail room

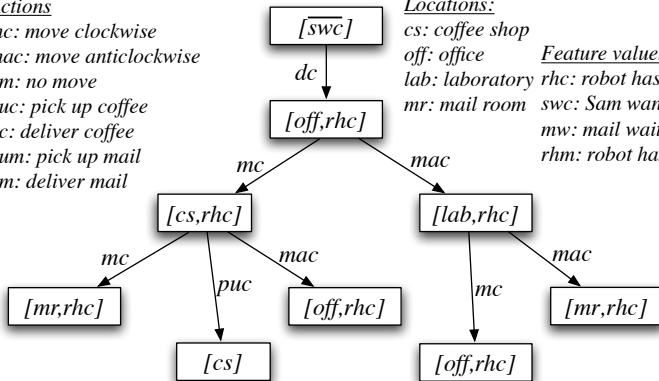

Feature values

rhc: robot has coffee

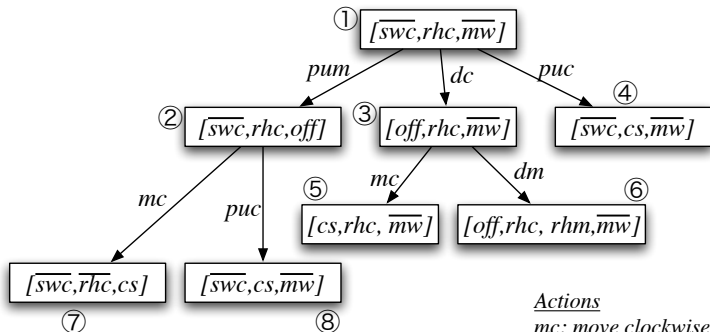

swc: Sam wants coffee

mw: mail waiting

rhm: robot has mail

Find the errors (none involve room locations)

Locations:

cs: coffee shop
 off: office
 lab: laboratory
 mr: mail room

Feature values

rhc: robot has coffee
 swc: Sam wants coffee
 mw: mail waiting
 rhm: robot has mail

Actions

mc: move clockwise
 mac: move anticlockwise
 nm: no move
 puc: pick up coffee
 dc: deliver coffee
 pum: pick up mail
 dm: deliver mail

Loop detection and multiple-path pruning

- Goal G_1 is simpler than goal G_2 if G_1 is a subset of G_2 .
 - It is easier to solve $[cs]$ than $[cs, rhc]$.
- **Loop detection:** if during the search we encounter a node N , but one of its ancestors N' is the same or simpler, you can prune N .
- **Multiple path pruning:** if during the search we encounter a node N , but elsewhere in the search tree (not as a descendent of N) we have encountered a node N' which is the same or simpler, you can prune N .

Improving Efficiency

- You can define a heuristic function that estimates how difficult it is to solve the goal from the initial state.
- You can use domain-specific knowledge to remove impossible goals.
 - E.g., it may not be obvious from the action description that the agent can only hold one item at any time.
