

TIDE TABLE CORRECTIONS

**A Program for the ALWAC III - E Computer
at the University of British Columbia.**

A. R. Dobell

May, 1961.

Purpose:

This program is intended to carry out the calculation of tidal differences on data for a given reference station, in order to obtain a corrected tide table applicable to nearby locations. The program accepts the input of correction factors and an initial date, and outputs the corrected data, with headings, in a form suitable for tabular printing.

Data Format:

The program accepts input of any one-line title followed by a single carriage return. It then expects constants and parameters in the following form.

$$\begin{array}{l} \frac{C_1}{\sqrt{x}} \{ \text{kk} \} \quad \left[\quad \frac{C_2}{\sqrt{x}} \{ \text{kk} \} \quad \left[\quad \frac{C_3}{r} \quad \left[\quad \text{xxxx} \dots \quad \left[\quad \frac{C_4}{r} \quad \left[\right. \right. \right. \right. \right. \\ \text{kk} \{ \text{h} \} \quad \left[\right. \\ \text{DDD} \{ \text{nn} \} \{ \text{MM} \} \quad \left[\right. \end{array}$$

These symbols have the following significances:

C_1 and C_2 are the time correction factors (in hours and minutes) for high and low tides respectively, and each consists of a sign (space or minus) followed by a single decimal digit, a space, and then the final two digits, terminated with any single dummy character. The next character should be a space if the corrections C_3 and C_4 (The height corrections) are additive, and should be an r if they are ratios.

The quantities $e_3' = 100c_3$ $e_4' = 100c_4$

are integers in the format of routine I - 35 -- i.e. - any number of decimal digits preceded by spaces, tabs, or carriage returns, and possibly a sign, and terminated by a single space, tab, or carriage return.

kk is to be a two digit decimal number specifying the number of days between stop codes on the output tape, and is followed by a single dummy character. The single digits 'h' or 'l' specify whether the initial tide is high or low, respectively, and are followed by a single dummy character. DDD is a set of three alphabetic digits giving the first three letters in the day of the week, nn is a two digit decimal number giving the date, and MM is a two digit decimal number specifying the month, of the tide to which the first reading on the data tape applies. DDD and nn should each be followed by spaces and MM followed either by a stop code or by any dummy character, as indicated below under OPERATING INSTRUCTIONS.

The data itself is to be in the form of a standard tide table, without headings - i. e. /

$$\text{tttt} \left[\dots \text{h}' \dots \left[\right. \right.$$

where tttt is a four digit number giving the time in hours and minutes, and terminated by a single dummy character, and the quantity

$$h' = 10h$$

where h is the height of the tide

is input in the format of I - 35 -i.e. - as an integer with any number of decimal digits preceded by space, tab, or carriage return, and possibly sign. Each line is followed by a single carriage return which serves as the terminating character for h'. An extra carriage return (that is, two in all) follows the last reading of each day.

Data for succeeding months at the same location should be input without further headings or parameter inputs.

One exception to the above format exists: if at any time the tides do not alternate - i.e. - if two successive high or low tides are encountered, the first must be terminated by a space, followed by a 'c', and then followed by one or two carriage returns as above.

Finally, at the end of a set of data for a single reference station, a terminating group of 12 characters must follow the final two carriage returns. The group

30(30(30(30(

is suggested.

Operating Instructions:

1. Set all console switches to NORMAL
Set Flexwriter-off-computer switch on the flexowriter to COMPUTER
Set Type -off- " " " " " " " "
Set Free-Isolate switch to ISOLATE
Turn Record switch ON
Turn High Speed Reader and High Speed Punch ON.
2. Place program tape in High Speed Reader (narrow side in to wall of reader)
Depress High Speed Clear switch on the high-speed console to CLEAR
3. There are then two modes of operations:
 - a) The correction factors and initial date for a single location may be punched at the beginning of the data tape for a reference station. In this case the dummy character following MM will not be a Stop code, and it is necessary only to place the data tape in the High Speed Reader (narrow side to the wall) and type on the flexowriter the entry code
CLEAR 4000 carriage return.
 - b) The correction factors and initial dates for several locations on the same reference station may be typed on a tape separate from the data tape for the reference station. In this case the dummy character following MM must be a stop code. The tape with correction factors and initial dates should be placed in the High Speed Reader, and the entry code
CLEAR 4000 carriage return
typed on the flexowriter. The program will stop after input of the information for one location; the data tape

3.
for the reference station may then be placed in the High Speed Reader, and the Start Read button on the High Speed console depressed.

4. In either mode of operation, the computer will halt on a 1b5f command at the end of each month's calculations. If the Jump-Normal-Proceed switch is depressed to PROCEED, the calculation will be continued for the same location and the subsequent month. Thus, if the Jump-Normal-Proceed switch is left in the PROCEED position, the calculations will continue until either the data is exhausted or the calculations to the end of the year are completed for the given location. Alternatively, if the Jump-Normal-Proceed switch is placed to JUMP, the program will be restarted, and will accept new titles, correction factors, and dates.
5. In printing the output tape, a tabular form with three columns may be convenient. For this format a value $kk = 11$ should be used during the calculations. When printing the output tape, the Flexowriter tab stops should be set at

8, 12, 21, 27, 36, 42.

The left margin stop should be set at 3 for the first column, 18, and 33, for the second and third respectively. At the foot of each column the flexowriter will stop, enabling the paper to be moved back to the top of the page, and the left margin to be reset.

Accuracy: The time reading is rounded to the nearest minute; the height readings are rounded to the nearest $1/10$ th of a foot.

Timing: Using the High Speed Reader and Punch, approximately $1\frac{1}{2}$ minutes is required for onemonth's calculations.

Subroutines: Channel 46 is the routine I - 31 adapted for use as a subroutine. The program uses also routine I - 35 stored in channel 12.

NOTE -- PROGRAM II

Several one-word changes are incorporated in a second program tape marked Tide Table Correction Program II. These changes enable the program to be used for the situation in which the height correction is of the form

$$h_{\text{corrected}} = ah_{\text{original}} + b$$

and a , b , are constants identical for both high and low tides. For this situation the input format is precisely the same as for program I, except that the character (space or 'r') indicating whether the correction is additive or multiplicative must be a space, and the entries

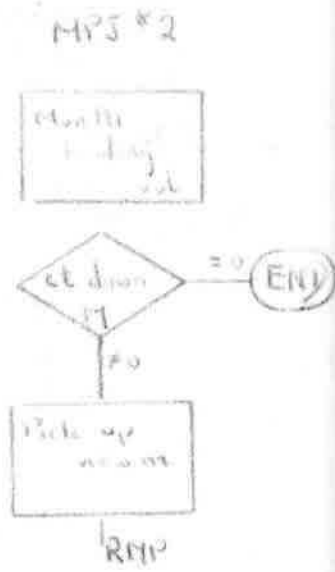

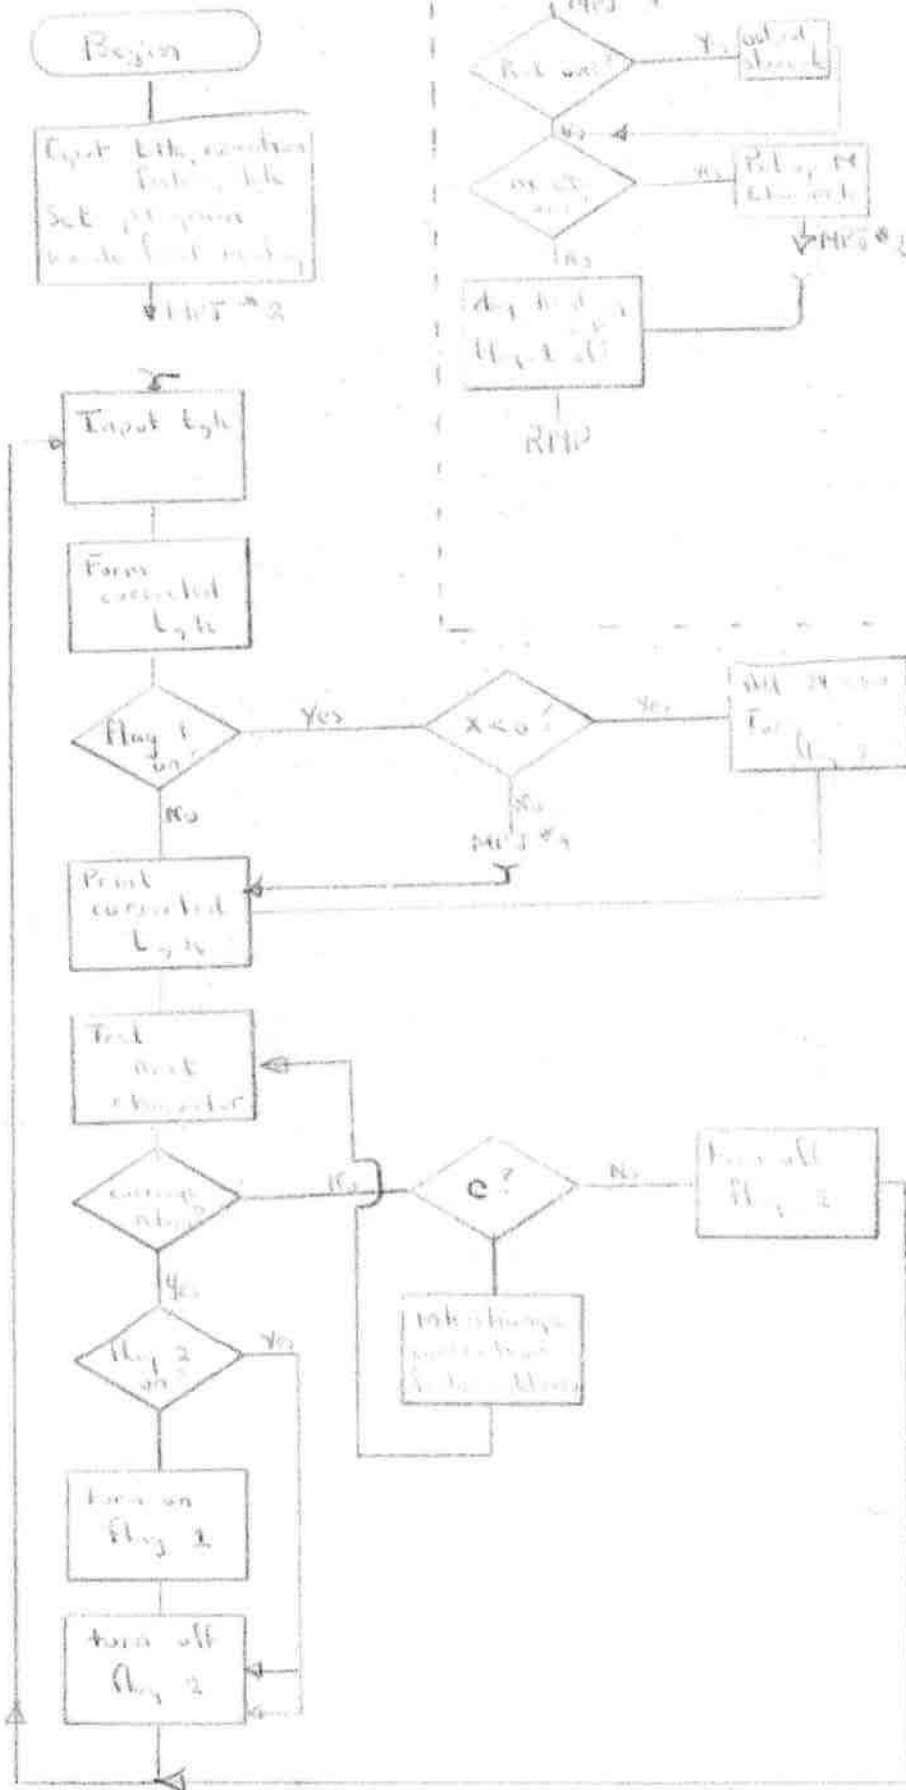

e_3' and e_4' of Program I

should be replaced by the quantities

$$a' = 100a \quad \text{and} \quad b' = 100b$$

respectively. The method of use is identical for both programs.
