

CSP Introduction

CPSC 322 Lecture 9

January 26, 2006
Textbook §3.0 – 3.2

Lecture Overview

- 1 Recap
- 2 Variables
- 3 Constraints

Branch-and-Bound Search Algorithm

- Follow exactly the same search path as **depth-first search**
 - treat the frontier as a stack: expand the most-recently added node first
 - the order in which neighbors are expanded can be governed by some arbitrary node-ordering heuristic
- Keep track of a **lower bound** and **upper bound** on solution cost at each node
 - **lower bound**: $LB(n) = cost(n) + h(n)$
 - **upper bound**: $UB = cost(n')$, where n' is the best solution found so far.
 - if no solution has been found yet, set the upper bound to ∞ .
- When a node n is selected for expansion:
 - if $LB(n) \geq UB$, remove n from frontier without expanding it
 - this is called “pruning the search tree” (really!)
 - else expand n , adding all of its neighbours to the frontier

Summary of Search Strategies

Strategy	Frontier Selection	Complete?	Space
Depth-first	Last node added	No	Linear
Breadth-first	First node added	Yes	Exp
Lowest-cost-first	Minimal $cost(n)$	Yes	Exp
Best-first	Global min $h(n)$	No	Exp
A^*	Minimal $f(n)$	Yes	Exp
Branch-and-Bound	Last node added, with pruning	No	Linear

Non-heuristic pruning

What can we prune besides nodes that are ruled out by our heuristic?

- Cycles
 - this one is really easy
- Multiple paths to the same node
 - if we want to maintain optimality, either keep the shortest path, or ensure that we always find the shortest path first

Other Search Ideas

The main problem with A^* is that it uses exponential space. Branch and bound was one way around this problem.

Two others are:

- Iterative deepening
- Memory-bounded A^*

Other search paradigms:

- Backwards search; bi-directional search
- Dynamic programming

Lecture Overview

- 1 Recap
- 2 Variables**
- 3 Constraints

States and Features

- In practical problems, there are usually too many states to reason about explicitly
- However, the states usually have some internal structure
 - this is why people can understand the problem in the first place!
- **Features:** a set of variables that together define the state of the world
- Many states can be described using few features:
 - 10 binary features \Rightarrow 1,024 states
 - 20 binary features \Rightarrow 1,048,576 states
 - 30 binary features \Rightarrow 1,073,741,824 states
 - 100 binary features \Rightarrow 1,267,650,600,228,229,401,496,703,205,376 states

Variables

- So, we define the state of the world as an assignment of values to a set of **variables**
 - variable: a synonym for feature
 - we denote variables using capital letters
 - each variable V has a domain $dom(V)$ of possible values
- Variables can be of several main kinds:
 - **Boolean**: $|dom(V)| = 2$
 - **Finite**: the domain contains a finite number of values
 - **Infinite but Discrete**: the domain is countably infinite
 - **Continuous**: e.g., real numbers between 0 and 1
- We'll call the set of states that are induced by a set of variables the set of **possible worlds**

Syntax and Semantics

- **Syntax:** the symbols that are manipulated by the computer, and the rules that are used to perform the manipulation
- **Semantics:** the meaning assigned to the symbols by the system designer
 - for example, the variable *black_queen_location* might correspond to the location on the chessboard of the black queen
- **Important point:** the computer only works at the syntactic level
 - it doesn't understand what the symbols mean!
 - things that seem obvious to us must be made explicit

Examples

- **Crossword Puzzle:**
 - variables are words that have to be filled in
 - domains are English words of the correct length
 - possible worlds: all ways of assigning words

Examples

- **Crossword Puzzle:**
 - variables are words that have to be filled in
 - domains are English words of the correct length
 - possible worlds: all ways of assigning words
- **Crossword 2:**
 - variables are cells (individual squares)
 - domains are letters of the alphabet
 - possible worlds: all ways of assigning letters to cells

Examples

- **Crossword Puzzle:**
 - variables are words that have to be filled in
 - domains are English words of the correct length
 - possible worlds: all ways of assigning words
- **Crossword 2:**
 - variables are cells (individual squares)
 - domains are letters of the alphabet
 - possible worlds: all ways of assigning letters to cells
- **Sudoku**
 - variables are cells
 - domains are numbers between 1 and 9
 - possible worlds: all ways of assigning numbers to cells

More Examples

- **Scheduling Problem:**
 - variables are different tasks that need to be scheduled (e.g., course in a university; job in a machine shop)
 - domains are the different combinations of times and locations for each task (e.g., time/room for course; time/machine for job)
 - possible worlds: time/location assignments for each task

More Examples

- **Scheduling Problem:**
 - variables are different tasks that need to be scheduled (e.g., course in a university; job in a machine shop)
 - domains are the different combinations of times and locations for each task (e.g., time/room for course; time/machine for job)
 - possible worlds: time/location assignments for each task
- **n -Queens problem**
 - variable: location of a queen on a chess board
 - there are n of them in total, hence the name
 - domains: grid coordinates
 - possible worlds: locations of all queens

Lecture Overview

- 1 Recap
- 2 Variables
- 3 Constraints**

Constraints

Constraints are restrictions on the values that one or more variables can take

- **Unary constraint:** restriction involving a single variable
 - of course, we could also achieve the same thing by using a smaller domain in the first place
- **k -ary constraint:** restriction involving the domains of k different variables
 - it turns out that k -ary constraints can always be represented as binary constraints, so we'll often talk about this case
- Constraints can be specified by
 - giving a list of valid domain values for each variable participating in the constraint
 - giving a function that returns true when given values for each variable which satisfy the constraint
- A possible world **satisfies** a set of constraints if the set of variables involved in each constraint take values that are consistent with that constraint

Examples

- **Crossword Puzzle:**
 - variables are words that have to be filled in
 - domains are valid English words
 - constraints: words have the same letters at points where they intersect
- **Crossword 2:**
 - variables are cells (individual squares)
 - domains are letters of the alphabet
 - constraints: sequences of letters form valid English words
- **Sudoku**
 - variables are cells
 - domains are numbers between 1 and 9
 - constraints: rows, columns, boxes contain all different numbers

More Examples

- **Scheduling Problem:**
 - variables are different tasks that need to be scheduled (e.g., course in a university; job in a machine shop)
 - domains are the different combinations of times and locations for each task (e.g., time/room for course; time/machine for job)
 - constraints: tasks can't be scheduled in the same location at the same time; certain tasks can't be scheduled in different locations at the same time; some tasks must come earlier than others; etc.
- **n -Queens problem**
 - variable: location of a queen on a chess board
 - domains: grid coordinates
 - constraints: no queen can attack another
